1. Introduction

The Yocto-PowerRelay module is a small 45x20mm module which allows you to control a small relay by USB. This relay can commute up to \$SPECMAXVOLT\$ and 5A, which allows you to pilot numerous low-voltage equipments by acting directly on their power supply. The module small dimensions enable it to be slipped almost anywhere, including inside the piloted equipment.

The Yocto-PowerRelay module

The Yocto-PowerRelay is intended to be used as laboratory equipment, or as industrial process-control equipment, but also for similar applications in domestic and commercial environments ¹.

Yoctopuce thanks you for buying this Yocto-PowerRelay and sincerely hopes that you will be satisfied with it. The Yoctopuce engineers have put a large amount of effort to ensure that your Yocto-PowerRelay is easy to install anywhere and easy to drive from a maximum of programming languages. If you are nevertheless disappointed with this module, do not hesitate to contact Yoctopuce support².

¹ i.e. the scope of IEC 61010-1:2010 international standard

² support@yoctopuce.com

1.1. Safety Information

Caution: The Yocto-PowerRelay is *not* certified for use in hazardous locations, explosive environments, or life-threatening applications.

Caution: The Yocto-PowerRelay is *not* certified for use in medical environments or life-support applications.

2. Presentation

2.1. Common elements

All Yocto-modules share a number of common functionalities.

USB connector

Yoctopuce modules all come with a micro-B USB socket. The corresponding cables are not the most common, but the sockets are the smallest available.

Warning: the USB connector is simply soldered in surface and can be pulled out if the USB plug acts as a lever. In this case, if the tracks stayed in position, the connector can be soldered back with a good iron and using flux to avoid bridges. Alternatively, you can solder a USB cable directly in the 1.27mm-spaced holes near the connector.

Yocto-button

The Yocto-button has two functionalities. First, it can activate the Yocto-beacon mode (see below under Yocto-led). Second, if you plug in a Yocto-module while keeping this button pressed, you can

then reprogram its firmware with a new version. Note that there is a simpler UI-based method to update the firmware, but this one works even in case of severely damaged firmware.

Yocto-led

Normally, the Yocto-led is used to indicate that the module is working smoothly. The Yocto-led then emits a low blue light which varies slowly, mimicking breathing. The Yocto-led stops breathing when the module is not communicating any more, as for instance when powered by a USB hub which is disconnected from any active computer.

When you press the Yocto-button, the Yocto-led switches to Yocto-beacon mode. It starts flashing faster with a stronger light, in order to facilitate the localization of a module when you have several identical ones. It is indeed possible to trigger off the Yocto-beacon by software, as it is possible to detect by software that a Yocto-beacon is on.

The Yocto-led has a third functionality, which is less pleasant: when the internal software which controls the module encounters a fatal error, the Yocto-led starts emitting an SOS in morse ¹. If this happens, unplug and re-plug the module. If it happens again, check that the module contains the latest version of the firmware, and, if it is the case, contact Yoctopuce support².

Current sensor

Each Yocto-module is able to measure its own current consumption on the USB bus. Current supply on a USB bus being quite critical, this functionality can be of great help. You can only view the current consumption of a module by software.

Serial number

Each Yocto-module has a unique serial number assigned to it at the factory. For Yocto-PowerRelay modules, this number starts with RELAYHI1. The module can be software driven using this serial number. The serial number cannot be modified.

Logical name

The logical name is similar to the serial number: it is a supposedly unique character string which allows you to reference your module by software. However, in the opposite of the serial number, the logical name can be modified at will. The benefit is to enable you to build several copies of the same project without needing to modify the driving software. You only need to program the same logical name in each copy. Warning: the behavior of a project becomes unpredictable when it contains several modules with the same logical name and when the driving software tries to access one of these modules through its logical name. When leaving the factory, modules do not have an assigned logical name. It is yours to define.

2.2. Specific elements

Screw terminal

The relay embedded in the Yocto-PowerRelay module is a commutator, which means that it can commute its input current onto one of two outputs. This is why the terminal has three poles: the input is at the center, and the outputs are on the outside. When the module is powered off, output A is active.

¹ short-short-short long-long-long short-short-short

² support@yoctopuce.com

Relay wiring inside the module.

Leds indicating the active output

On each side of the terminal, there are green leds which indicate which module output is active. By default, the light of these leds is rather strong, but you can change their luminosity by software.

2.3. Optional accessories

The accessories below are not necessary to use the Yocto-PowerRelay module but might be useful depending on your project. These are mostly common products that you can buy from your favorite hacking store. To save you the tedious job of looking for them, most of them are also available on the Yoctopuce shop.

Screws and spacers

In order to mount the Yocto-PowerRelay module, you can put small screws in the 2.5mm assembly holes, with a screw head no larger than 4.5mm. The best way is to use threaded spacers, which you can then mount wherever you want. You can find more details on this topic in the chapter about assembly and connections.

Micro-USB hub

If you intend to put several Yoctopuce modules in a very small space, you can connect them directly to a micro-USB hub. Yoctopuce builds a USB hub particularly small for this purpose (down to 20mmx36mm), on which you can directly solder a USB cable instead of using a USB plug. For more details, see the micro-USB hub information sheet.

YoctoHub-Ethernet, YoctoHub-Wireless and YoctoHub-GSM

You can add network connectivity to your Yocto-PowerRelay, thanks to the YoctoHub-Ethernet, the YoctoHub-Wireless and the YoctoHub-GSM which provides respectively Ethernet, WiFi and GSM connectivity. All of them can drive up to three devices and behave exactly like a regular computer running a *VirtualHub*.

1.27mm (or 1.25mm) connectors

In case you wish to connect your Yocto-PowerRelay to a Micro-hub USB or a YoctoHub without using a bulky USB connector, you can use the four 1.27mm pads just behind the USB connector. There are two options.

You can mount the Yocto-PowerRelay directly on the hub using screw and spacers, and connect it using 1.27mm board-to-board connectors. To prevent shortcuts, it is best to solder the female connector on the hub and the male connector on the Yocto-PowerRelay.

You can also use a small 4-wires cable with a 1.27mm connector. 1.25mm works as well, it does not make a difference for 4 pins. This makes it possible to move the device a few inches away. Don't put

it too far away if you use that type of cable, because as the cable is not shielded, it may cause undesirable electromagnetic emissions.

Enclosure

Your Yocto-PowerRelay has been designed to be installed as is in your project. Nevertheless, Yoctopuce sells enclosures specifically designed for Yoctopuce devices. These enclosures have removable mounting brackets and magnets allowing them to stick on ferromagnetic surfaces. More details are available on the Yoctopuce web site ³. The suggested enclosure model for your Yocto-PowerRelay is the YoctoBox-Short-Thick-Black.

You can install your Yocto-PowerRelay in an optional enclosure

³ <http://www.yoctopuce.com/EN/products/category/enclosures>

3. First steps

By design, all Yoctopuce modules are driven the same way. Therefore, user's guides for all the modules of the range are very similar. If you have already carefully read through the user's guide of another Yoctopuce module, you can jump directly to the description of the module functions.

3.1. Prerequisites

In order to use your Yocto-PowerRelay module, you should have the following items at hand.

A computer

Yoctopuce modules are intended to be driven by a computer (or possibly an embedded microprocessor). You will write the control software yourself, according to your needs, using the information provided in this manual.

Yoctopuce provides software libraries to drive its modules for the following operating systems: Windows, Mac OS X, Linux, and Android. Yoctopuce modules do not require installing any specific system driver, as they leverage the standard HID driver¹ provided with every operating system.

Windows versions currently supported are: Windows XP, Windows 2003, Windows Vista, Windows 7, Windows 8 and Windows 10. Both 32 bit and 64 bit versions are supported. Yoctopuce is frequently testing its modules on Windows 7 and Windows 10.

Mac OS X versions currently supported are: 10.9 (Maverick), 10.10 (Yosemite), 10.11 (El Capitan) and 10.12 (Sierra). Yoctopuce is frequently testing its modules on Mac OS X 10.11.

Linux kernels currently supported are the 2.6 branch, the 3.0 branch and the 4.0 branch. Other versions of the Linux kernel, and even other UNIX variants, are very likely to work as well, as Linux support is implemented through the standard **libusb** API. Yoctopuce is frequently testing its modules on Linux kernel 3.19.

Android versions currently supported are: Android 3.1 and later. Moreover, it is necessary for the tablet or phone to support the *Host* USB mode. Yoctopuce is frequently testing its modules on Android 4.x on a Nexus 7 and a Samsung Galaxy S3 with the Java for Android library.

A USB cable, type A-micro B

USB connectors exist in three sizes: the "standard" size that you probably use to connect your printer, the very common mini size to connect small devices, and finally the micro size often used to

¹ The HID driver is the one that takes care of the mouse, the keyboard, etc.

connect mobile phones, as long as they do not exhibit an apple logo. All USB modules manufactured by Yoctopuce use micro size connectors.

The most common USB 2 connectors: A, B, Mini B, Micro A, Micro B.²

To connect your Yocto-PowerRelay module to a computer, you need a USB cable of type A-micro B. The price of this cable may vary a lot depending on the source, look for it under the name *USB A to micro B Data cable*. Make sure not to buy a simple USB charging cable without data connectivity. The correct type of cable is available on the Yoctopuce shop.

You must plug in your Yocto-PowerRelay module with a USB cable of type A - micro B.

If you insert a USB hub between the computer and the Yocto-PowerRelay module, make sure to take into account the USB current limits. If you do not, be prepared to face unstable behaviors and unpredictable failures. You can find more details on this topic in the chapter about assembly and connections.

3.2. Testing USB connectivity

At this point, your Yocto-PowerRelay should be connected to your computer, which should have recognized it. It is time to make it work.

Go to the Yoctopuce web site and download the *Virtual Hub* software³. It is available for Windows, Linux, and Mac OS X. Normally, the Virtual Hub software serves as an abstraction layer for languages which cannot access the hardware layers of your computer. However, it also offers a succinct interface to configure your modules and to test their basic functions. You access this interface with a simple web browser⁴. Start the *Virtual Hub* software in a command line, open your preferred web browser and enter the URL `http://127.0.0.1:4444`. The list of the Yoctopuce modules connected to your computer is displayed.

² Although they existed for some time, Mini A connectors are not available anymore http://www.usb.org/developers/Deprecation_Announcement_052507.pdf

³ www.yoctopuce.com/EN/virtualhub.php

⁴ The interface is tested on Chrome, FireFox, Safari, Edge et IE 11.

Serial	Logical Name	Description	Action
VIRTHUB0-7d1a86fb		VirtualHub	beacon configure view log file
RELAYHI1-00022		Yocto-PowerRelay	beacon configure view log file

Module list as displayed in your web browser.

3.3. Localization

You can then physically localize each of the displayed modules by clicking on the **beacon** button. This puts the Yocto-led of the corresponding module in Yocto-beacon mode. It starts flashing, which allows you to easily localize it. The second effect is to display a little blue circle on the screen. You obtain the same behavior when pressing the Yocto-button of the module.

3.4. Test of the module

The first item to check is that your module is working well: click on the serial number corresponding to your module. This displays a window summarizing the properties of your Yocto-PowerRelay.

Properties of the Yocto-PowerRelay module.

This window allows you, among other things, to test the relay with the **switch to A / switch to B** button. There is a characteristic clicking when the relay is working. Moreover, the led indicating the active output lights up. Notice that the module consumption is about 25 mA when the relay is idle (output A selected) and about 65 mA when the relay is active (output B selected).

3.5. Configuration

When, in the module list, you click on the **configure** button corresponding to your module, the configuration window is displayed.

Yocto-PowerRelay module configuration.

Firmware

The module firmware can easily be updated with the help of the interface. Firmware destined for Yoctopuce modules are available as .byn files and can be downloaded from the Yoctopuce web site.

To update a firmware, simply click on the **upgrade** button on the configuration window and follow the instructions. If the update fails for one reason or another, unplug and re-plug the module and start the update process again. This solves the issue in most cases. If the module was unplugged while it was being reprogrammed, it does probably not work anymore and is not listed in the interface. However, it is always possible to reprogram the module correctly by using the *Virtual Hub* software⁵ in command line⁶.

Logical name of the module

The logical name is a name that you choose, which allows you to access your module, in the same way a file name allows you to access its content. A logical name has a maximum length of 19 characters. Authorized characters are A..Z, a..z, 0..9, _, and -. If you assign the same logical name to two modules connected to the same computer and you try to access one of them through this logical name, behavior is undetermined: you have no way of knowing which of the two modules answers.

Luminosity

This parameter allows you to act on the maximal intensity of the leds of the module. This enables you, if necessary, to make it a little more discreet, while limiting its power consumption. Note that this parameter acts on all the signposting leds of the module, including the Yocto-led. If you connect a module and no led turns on, it may mean that its luminosity was set to zero.

Logical names of functions

Each Yoctopuce module has a serial number and a logical name. In the same way, each function on each Yoctopuce module has a hardware name and a logical name, the latter can be freely chosen by the user. Using logical names for functions provides a greater flexibility when programming modules.

The only function of the Yocto-PowerRelay module is its embedded relay, with the hardware name "relay1".

⁵ www.yoctopuce.com/EN/virtualhub.php

⁶ More information available in the virtual hub documentation

4. Assembly and connections

This chapter provides important information regarding the use of the Yocto-PowerRelay module in real-world situations. Make sure to read it carefully before going too far into your project if you want to avoid pitfalls.

4.1. Fixing

While developing your project, you can simply let the module hang at the end of its cable. Check only that it does not come in contact with any conducting material (such as your tools). When your project is almost at an end, you need to find a way for your modules to stop moving around.

Examples of assembly on supports

The Yocto-PowerRelay module contains 2.5mm assembly holes. You can use these holes for screws. The screw head diameter must not be larger than 4.5mm or they will damage the module circuits. Make sure that the lower surface of the module is not in contact with the support. We recommend using spacers, but other methods are possible. Nothing prevents you from fixing the module with a glue gun; it will not be good-looking, but it will hold.

4.2. Assembly examples

If you obtained this Yocto-PowerRelay module, it is probably because you know exactly what you intend to do with it. You can nevertheless find below a few wiring examples, among the simplest.

Pilot a light bulb with your Yocto-PowerRelay module.

Pilot two light bulbs in alternation with your Yocto-PowerRelay module.

4.3. Electro-magnetic relays and coils

Some devices that you may wish to control with your Yocto-PowerRelay module contain large coils. It is in particular the case for electric motors and transformers. This may cause trouble because of the auto-induction generated when current goes through a coil. A very high voltage briefly appears at the ends of a coil when one brutally cuts the current passing through it. This high voltage can create an electric arc where the circuit was cut, in our case inside the relay soldered on the module. This electric arc can eat away the relay connections, leading to premature aging.

Therefore, we advise against controlling electric motors or transformers with an electro-magnetic relay, be it a Yocto-PowerRelay module, or any other command system based on this technology.

It is possible to limit this phenomenon by inserting a TVS diode in parallel with the device containing the coil. These diodes are blocking below a specified voltage, and conductive beyond. So if you clamp one of these diodes on your inductive load, this will short cut voltage peaks. You only have to choose a diode with the right clamping voltage for your application. If you wish to know more, Tyco published an application note about this ¹.

Controlling an electric motor with a relay, using a protecting diode.

4.4. USB power distribution

Although USB means *Universal Serial BUS*, USB devices are not physically organized as a flat bus but as a tree, using point-to-point connections. This has consequences on power distribution: to make it simple, every USB port must supply power to all devices directly or indirectly connected to it. And USB puts some limits.

In theory, a USB port provides 100mA, and may provide up to 500mA if available and requested by the device. In the case of a hub without external power supply, 100mA are available for the hub itself, and the hub should distribute no more than 100mA to each of its ports. This is it, and this is not much. In particular, it means that in theory, it is not possible to connect USB devices through two

¹ Relay contact life, Application note, Tyco electronics, http://relays.te.com/appnotes/app_pdfs/13c3236.pdf

cascaded hubs without external power supply. In order to cascade hubs, it is necessary to use self-powered USB hubs, that provide a full 500mA to each subport.

In practice, USB would not have been as successful if it was really so picky about power distribution. As it happens, most USB hub manufacturers have been doing savings by not implementing current limitation on ports: they simply connect the computer power supply to every port, and declare themselves as *self-powered hub* even when they are taking all their power from the USB bus (in order to prevent any power consumption check in the operating system). This looks a bit dirty, but given the fact that computer USB ports are usually well protected by a hardware current limitation around 2000mA, it actually works in every day life, and seldom makes hardware damage.

What you should remember: if you connect Yoctopuce modules through one, or more, USB hub without external power supply, you have no safe-guard and you depend entirely on your computer manufacturer attention to provide as much current as possible on the USB ports, and to detect overloads before they lead to problems or to hardware damages. When modules are not provided enough current, they may work erratically and create unpredictable bugs. If you want to prevent any risk, do not cascade hubs without external power supply, and do not connect peripherals requiring more than 100mA behind a bus-powered hub.

In order to help controlling and planning overall power consumption for your project, all Yoctopuce modules include a built-in current sensor that tells (with 5mA precision) the consumption of the module on the USB bus.

5. Programming, general concepts

The Yoctopuce API was designed to be at the same time simple to use and sufficiently generic for the concepts used to be valid for all the modules in the Yoctopuce range, and this in all the available programming languages. Therefore, when you have understood how to drive your Yocto-PowerRelay with your favorite programming language, learning to use another module, even with a different language, will most likely take you only a minimum of time.

5.1. Programming paradigm

The Yoctopuce API is object oriented. However, for simplicity's sake, only the basics of object programming were used. Even if you are not familiar with object programming, it is unlikely that this will be a hinderance for using Yoctopuce products. Note that you will never need to allocate or deallocate an object linked to the Yoctopuce API: it is automatically managed.

There is one class per Yoctopuce function type. The name of these classes always starts with a Y followed by the name of the function, for example *YTemperature*, *YRelay*, *YPressure*, etc.. There is also a *YModule* class, dedicated to managing the modules themselves, and finally there is the static *YAPI* class, that supervises the global workings of the API and manages low level communications.

Structure of the Yoctopuce API.

The YSensor class

Each Yoctopuce sensor function has its dedicated class: *YTemperature* to measure the temperature, *YVoltage* to measure a voltage, *YRelay* to drive a relay, etc. However there is a special class that can do more: *YSensor*.

The YSensor class is the parent class for all Yoctopuce sensors, and can provide access to any sensor, regardless of its type. It includes methods to access all common functions. This makes it easier to create applications that use many different sensors. Moreover, if you create an application based on YSensor, it will work with all Yoctopuce sensors, even those which do not yet exist.

Programmation

In the Yoctopuce API, priority was put on the ease of access to the module functions by offering the possibility to make abstractions of the modules implementing them. Therefore, it is quite possible to work with a set of functions without ever knowing exactly which module are hosting them at the hardware level. This tremendously simplifies programming projects with a large number of modules.

From the programming stand point, your Yocto-PowerRelay is viewed as a module hosting a given number of functions. In the API, these functions are objects which can be found independently, in several ways.

Access to the functions of a module

Access by logical name

Each function can be assigned an arbitrary and persistent logical name: this logical name is stored in the flash memory of the module, even if this module is disconnected. An object corresponding to an Xxx function to which a logical name has been assigned can then be directly found with this logical name and the *YXxx.FindXxx* method. Note however that a logical name must be unique among all the connected modules.

Access by enumeration

You can enumerate all the functions of the same type on all the connected modules with the help of the classic enumeration functions *FirstXxx* and *nextXxxx* available for each *YXxx* class.

Access by hardware name

Each module function has a hardware name, assigned at the factory and which cannot be modified. The functions of a module can also be found directly with this hardware name and the *YXxx.FindXxx* function of the corresponding class.

Difference between *Find* and *First*

The *YXxx.FindXxxx* and *YXxx.FirstXxxx* methods do not work exactly the same way. If there is no available module, *YXxx.FirstXxxx* returns a null value. On the opposite, even if there is no corresponding module, *YXxx.FindXxxx* returns a valid object, which is not online but which could become so if the corresponding module is later connected.

Function handling

When the object corresponding to a function is found, its methods are available in a classic way. Note that most of these subfunctions require the module hosting the function to be connected in order to be handled. This is generally not guaranteed, as a USB module can be disconnected after the control software has started. The *isOnline* method, available in all the classes, is then very helpful.

Access to the modules

Even if it is perfectly possible to build a complete project while making a total abstraction of which function is hosted on which module, the modules themselves are also accessible from the API. In fact, they can be handled in a way quite similar to the functions. They are assigned a serial number at the factory which allows you to find the corresponding object with *YModule.Find()*. You can also assign arbitrary logical names to the modules to make finding them easier. Finally, the *YModule* class contains the *YModule.FirstModule()* and *nextModule()* enumeration methods allowing you to list the connected modules.

Functions/Module interaction

From the API standpoint, the modules and their functions are strongly uncorrelated by design. Nevertheless, the API provides the possibility to go from one to the other. Thus, the `get_module()` method, available for each function class, allows you to find the object corresponding to the module hosting this function. Inversely, the `YModule` class provides several methods allowing you to enumerate the functions available on a module.

5.2. The Yocto-PowerRelay module

The Yocto-PowerRelay module provides a single instances of the Relay function, corresponding to the high-power relay present on the module.

5.3. Module control interface

This interface is identical for all Yoctopuce USB modules. It can be used to control the module global parameters, and to enumerate the functions provided by each module.

productName

Character string containing the commercial name of the module, as set by the factory.

serialNumber

Character string containing the serial number, unique and programmed at the factory. For a Yocto-PowerRelay module, this serial number always starts with RELAYHI1. You can use the serial number to access a given module by software.

logicalName

Character string containing the logical name of the module, initially empty. This attribute can be modified at will by the user. Once initialized to a non-empty value, it can be used to access a given module. If two modules with the same logical name are in the same project, there is no way to determine which one answers when one tries accessing by logical name. The logical name is limited to 19 characters among A..Z, a..z, 0..9, _, and -.

productId

USB device identifier of the module, preprogrammed to 13 at the factory.

productRelease

Release number of the module hardware, preprogrammed at the factory.

firmwareRelease

Release version of the embedded firmware, changes each time the embedded software is updated.

persistentSettings

State of persistent module settings: loaded from flash memory, modified by the user or saved to flash memory.

luminosity

Lighting strength of the informative leds (e.g. the Yocto-Led) contained in the module. It is an integer value which varies between 0 (leds turned off) and 100 (maximum led intensity). The default value is 50. To change the strength of the module leds, or to turn them off completely, you only need to change this value.

beacon

Activity of the localization beacon of the module.

upTime

Time elapsed since the last time the module was powered on.

usbCurrent

Current consumed by the module on the USB bus, in milli-amps.

rebootCountdown

Countdown to use for triggering a reboot of the module.

userVar

32bit integer variable available for user storage.

5.4. Relay function interface

The Yoctopuce application programming interface allows you to switch the relay state. This change is not persistent: the relay will automatically return to its idle position whenever power is lost or if the module is restarted. The library can also generate automatically short pulses of determined duration. On devices with two output for each relay (double throw), the two outputs are named A and B, with output A corresponding to the idle position (at power off) and the output B corresponding to the active state. If you prefer the alternate default state, simply switch your cables on the board.

logicalName

Character string containing the logical name of the relay, initially empty. This attribute can be modified at will by the user. Once initialized to a non-empty value, it can be used to access the relay

directly. If two relays with the same logical name are used in the same project, there is no way to determine which one answers when one tries accessing by logical name. The logical name is limited to 19 characters among A..Z, a..z, 0..9, _, and -.

advertisedValue

Short character string summarizing the current state of the relay, that will be automatically advertised up to the parent hub. For a relay, the advertised value is the the relays state (A for the idle position, B for the active position).

state

Active output of the relays: A for the idle position, B for the active position.

stateAtPowerOn

Active output of the relays at device power on: A for the idle position, B for the active position, UNCHANGED to leave the relay as is.

maxTimeOnStateA

Maximum time (ms) allowed for relays to stay in state A before automatically switching back in to B state. Zéro means no maximum time.

maxTimeOnStateB

Maximum time (ms) allowed for relays to stay in state B before automatically switching back in to A state. Zéro means no maximum time.

output

Output state of the relays, when used as a simple switch (single throw).

pulseTimer

Time during which the relays should be kept in state B (active) before returning automatically to state A (idle state). Any explicit state change issued afterwards will cancel the automated switch.

delayedPulseTimer

Delayed pulse parameters.

countdown

Waiting delay before next pulse (delayed pulse case).

5.5. What interface: Native, DLL or Service ?

There are several methods to control you Yoctopuce module by software.

Native control

In this case, the software driving your project is compiled directly with a library which provides control of the modules. Objectively, it is the simplest and most elegant solution for the end user. The end user then only needs to plug the USB cable and run your software for everything to work. Unfortunately, this method is not always available or even possible.

The application uses the native library to control the locally connected module

Native control by DLL

Here, the main part of the code controlling the modules is located in a DLL. The software is compiled with a small library which provides control of the DLL. It is the fastest method to code module support in a given language. Indeed, the "useful" part of the control code is located in the DLL which is the same for all languages: the effort to support a new language is limited to coding the small library which controls the DLL. From the end user stand point, there are few differences: one must simply make sure that the DLL is installed on the end user's computer at the same time as the main software.

The application uses the DLL to natively control the locally connected module

Control by service

Some languages do simply not allow you to easily gain access to the hardware layers of the machine. It is the case for Javascript, for instance. To deal with this case, Yoctopuce provides a solution in the form of a small piece of software called *VirtualHub*¹. It can access the modules, and your application only needs to use a library which offers all necessary functions to control the modules via this VirtualHub. The end users will have to start the VirtualHub before running the project control software itself, unless they decide to install the hub as a service/deamon, in which case the VirtualHub starts automatically when the machine starts up.

¹ www.yoctopuce.com/EN/virtualhub.php

The application connects itself to the VirtualHub to gain access to the module

The service control method comes with a non-negligible advantage: the application does not need to run on the machine on which the modules are connected. The application can very well be located on another machine which connects itself to the service to drive the modules. Moreover, the native libraries and DLL mentioned above are also able to connect themselves remotely to one or several machines running VirtualHub.

When a VirtualHub is used, the control application does not need to reside on the same machine as the module.

Whatever the selected programming language and the control paradigm used, programming itself stays strictly identical. From one language to another, functions bear exactly the same name, and have the same parameters. The only differences are linked to the constraints of the languages themselves.

Language	Native	Native with DLL	Virtual hub
C++	✓	✓	✓
Objective-C	✓	-	✓
Delphi	-	✓	✓
Python	-	✓	✓
VisualBasic .Net	-	✓	✓
C# .Net	-	✓	✓
EcmaScript / JavaScript	-	-	✓
PHP	-	-	✓
Java	-	✓	✓
Java for Android	✓	-	✓
Command line	✓	-	✓

Support methods for different languages

Limitations of the Yoctopuce libraries

Natives et DLL libraries have a technical limitation. On the same computer, you cannot concurrently run several applications accessing Yoctopuce devices directly. If you want to run several projects on the same computer, make sure your control applications use Yoctopuce devices through a *VirtualHub* software. The modification is trivial: it is just a matter of parameter change in the `yRegisterHub()` call.

5.6. Programming, where to start?

At this point of the user's guide, you should know the main theoretical points of your Yocto-PowerRelay. It is now time to practice. You must download the Yoctopuce library for your favorite programming language from the Yoctopuce web site². Then skip directly to the chapter corresponding to the chosen programming language.

All the examples described in this guide are available in the programming libraries. For some languages, the libraries also include some complete graphical applications, with their source code.

When you have mastered the basic programming of your module, you can turn to the chapter on advanced programming that describes some techniques that will help you make the most of your Yocto-PowerRelay.

² <http://www.yoctopuce.com/EN/libraries.php>

6. Using the Yocto-PowerRelay in command line

When you want to perform a punctual operation on your Yocto-PowerRelay, such as reading a value, assigning a logical name, and so on, you can obviously use the Virtual Hub, but there is a simpler, faster, and more efficient method: the command line API.

The command line API is a set of executables, one by type of functionality offered by the range of Yoctopuce products. These executables are provided pre-compiled for all the Yoctopuce officially supported platforms/OS. Naturally, the executable sources are also provided¹.

6.1. Installing

Download the command line API². You do not need to run any setup, simply copy the executables corresponding to your platform/OS in a directory of your choice. You may add this directory to your PATH variable to be able to access these executables from anywhere. You are all set, you only need to connect your Yocto-PowerRelay, open a shell, and start working by typing for example:

```
C:\>YRelay any set_state B
```

To use the command API on Linux, you need either have root privileges or to define an *udev* rule for your system. See the *Troubleshooting* chapter for more details.

6.2. Use: general description

All the command line API executables work on the same principle. They must be called the following way

```
C:\>Executable [options] [target] command [parameter]
```

[options] manage the global workings of the commands, they allow you, for instance, to pilot a module remotely through the network, or to force the module to save its configuration after executing the command.

[target] is the name of the module or of the function to which the command applies. Some very generic commands do not need a target. You can also use the aliases "*any*" and "*all*", or a list of names separated by comas without space.

¹ If you want to recompile the command line API, you also need the C++ API.

² <http://www.yoctopuce.com/EN/libraries.php>

`command` is the command you want to run. Almost all the functions available in the classic programming APIs are available as commands. You need to respect neither the case nor the underlined characters in the command name.

[parameters] logically are the parameters needed by the command.

At any time, the command line API executables can provide a rather detailed help. Use for instance:

```
C:\>executable /help
```

to know the list of available commands for a given command line API executable, or even:

```
C:\>executable command /help
```

to obtain a detailed description of the parameters of a command.

6.3. Control of the Relay function

To control the Relay function of your Yocto-PowerRelay, you need the YRelay executable file.

For instance, you can launch:

```
C:\>YRelay any set_state B
```

This example uses the *"any"* target to indicate that we want to work on the first Relay function found among all those available on the connected Yoctopuce modules when running. This prevents you from having to know the exact names of your function and of your module.

But you can use logical names as well, as long as you have configured them beforehand. Let us imagine a Yocto-PowerRelay module with the *RELAYHI1-123456* serial number which you have called *"MyModule"*, and its relay1 function which you have renamed *"MyFunction"*. The five following calls are strictly equivalent (as long as *MyFunction* is defined only once, to avoid any ambiguity).

```
C:\>YRelay RELAYHI1-123456.relay1 describe
C:\>YRelay RELAYHI1-123456.MyFunction describe
C:\>YRelay MyModule.relay1 describe
C:\>YRelay MyModule.MyFunction describe
C:\>YRelay MyFunction describe
```

To work on all the Relay functions at the same time, use the *"all"* target.

```
C:\>YRelay all describe
```

For more details on the possibilities of the YRelay executable, use:

```
C:\>YRelay /help
```

6.4. Control of the module part

Each module can be controlled in a similar way with the help of the YModule executable. For example, to obtain the list of all the connected modules, use:

```
C:\>YModule inventory
```

You can also use the following command to obtain an even more detailed list of the connected modules:

```
C:\>YModule all describe
```

Each `xxx` property of the module can be obtained thanks to a command of the `get_xxxx()` type, and the properties which are not read only can be modified with the `set_xxx()` command. For example:

```
C:\>YModule RELAYHI1-12346 set_logicalName MonPremierModule
C:\>YModule RELAYHI1-12346 get_logicalName
```

Changing the settings of the module

When you want to change the settings of a module, simply use the corresponding `set_xxx` command. However, this change happens only in the module RAM: if the module restarts, the changes are lost. To store them permanently, you must tell the module to save its current configuration in its nonvolatile memory. To do so, use the `saveToFlash` command. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash` method. For example:

```
C:\>YModule RELAYHI1-12346 set_logicalName MonPremierModule
C:\>YModule RELAYHI1-12346 saveToFlash
```

Note that you can do the same thing in a single command with the `-s` option.

```
C:\>YModule -s RELAYHI1-12346 set_logicalName MonPremierModule
```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

6.5. Limitations

The command line API has the same limitation than the other APIs: there can be only one application at a given time which can access the modules natively. By default, the command line API works in native mode.

You can easily work around this limitation by using a Virtual Hub: run the VirtualHub³ on the concerned machine, and use the executables of the command line API with the `-r` option. For example, if you use:

```
C:\>YModule inventory
```

you obtain a list of the modules connected by USB, using a native access. If another command which accesses the modules natively is already running, this does not work. But if you run a Virtual Hub, and you give your command in the form:

```
C:\>YModule -r 127.0.0.1 inventory
```

it works because the command is not executed natively anymore, but through the Virtual Hub. Note that the Virtual Hub counts as a native application.

³ <http://www.yoctopuce.com/EN/virtualhub.php>

7. Using Yocto-PowerRelay with JavaScript / EcmaScript

EcmaScript is the official name of the standardized version of the web-oriented programming language commonly referred to as *JavaScript*. This Yoctopuce library take advantages of advanced features introduced in EcmaScript 2017. It has therefore been named *Library for JavaScript / EcmaScript 2017* to differentiate it from the previous *Library for JavaScript*, now deprecated in favor of this new version.

This library provides access to Yoctopuce devices for modern JavaScript engines. It can be used within a browser as well as with Node.js. The library will automatically detect upon initialization whether the runtime environment is a browser or a Node.js virtual machine, and use the most appropriate system libraries accordingly.

Asynchronous communication with the devices is handled across the whole library using Promise objects, leveraging the new EcmaScript 2017 `async / await` non-blocking syntax for asynchronous I/O (see below). This syntax is now available out-of-the-box in most Javascript engines. No transpilation is needed: no Babel, no jspm, just plain Javascript. Here is your favorite engines minimum version needed to run this code. All of them are officially released at the time we write this document.

- Node.js v7.6 and later
- Firefox 52
- Opera 42 (incl. Android version)
- Chrome 55 (incl. Android version)
- Safari 10.1 (incl. iOS version)
- Android WebView 55
- Google V8 Javascript engine v5.5

If you need backward-compatibility with older releases, you can always run Babel to transpile your code and the library to older standards, as described a few paragraphs below.

We don't suggest using `jspm 0.17` anymore since that tool is still in Beta after 18 month, and having to use an extra tool to implement our library is pointless now that `async / await` are part of the standard.

7.1. Blocking I/O versus Asynchronous I/O in JavaScript

JavaScript is single-threaded by design. That means, if a program is actively waiting for the result of a network-based operation such as reading from a sensor, the whole program is blocked. In browser environments, this can even completely freeze the user interface. For this reason, the use of blocking

I/O in JavaScript is strongly discouraged nowadays, and blocking network APIs are getting deprecated everywhere.

Instead of using parallel threads, JavaScript relies on asynchronous I/O to handle operations with a possible long timeout: whenever a long I/O call needs to be performed, it is only triggered and but then the code execution flow is terminated. The JavaScript engine is therefore free to handle other pending tasks, such as UI. Whenever the pending I/O call is completed, the system invokes a callback function with the result of the I/O call to resume execution of the original execution flow.

When used with plain callback functions, as pervasive in Node.js libraries, asynchronous I/O tend to produce code with poor readability, as the execution flow is broken into many disconnected callback functions. Fortunately, new methods have emerged recently to improve that situation. In particular, the use of *Promise* objects to abstract and work with asynchronous tasks helps a lot. Any function that makes a long I/O operation can return a *Promise*, which can be used by the caller to chain subsequent operations in the same flow. Promises are part of EcmaScript 2015 standard.

Promise objects are good, but what makes them even better is the new `async / await` keywords to handle asynchronous I/O:

- a function declared `async` will automatically encapsulate its result as a Promise
- within an `async` function, any function call prefixed with `await` will chain the Promise returned by the function with a promise to resume execution of the caller
- any exception during the execution of an `async` function will automatically invoke the Promise failure continuation

Long story made short, `async` and `await` make it possible to write EcmaScript code with all benefits of asynchronous I/O, but without breaking the code flow. It is almost like multi-threaded execution, except that control switch between pending tasks only happens at places where the `await` keyword appears.

We have therefore chosen to write our new EcmaScript library using Promises and `async` functions, so that you can use the friendly `await` syntax. To keep it easy to remember, **all public methods** of the EcmaScript library **are `async`**, i.e. return a Promise object, **except**:

- `GetTickCount()`, because returning a time stamp asynchronously does not make sense...
- `FindModule()`, `FirstModule()`, `nextModule()`,... because device detection and enumeration always work on internal device lists handled in background, and does not require immediate asynchronous I/O.

7.2. Using Yoctopuce library for JavaScript / EcmaScript 2017

JavaScript is one of those languages which do not generally allow you to directly access the hardware layers of your computer. Therefore the library can only be used to access network-enabled devices (connected through a YoctoHub), or USB devices accessible through Yoctopuce TCP/IP to USB gateway, named *VirtualHub*.

Go to the Yoctopuce web site and download the following items:

- The Javascript / EcmaScript 2017 programming library¹
- The VirtualHub software² for Windows, Mac OS X or Linux, depending on your OS

Extract the library files in a folder of your choice, you will find many of examples in it. Connect your modules and start the VirtualHub software. You do not need to install any driver.

Using the official Yoctopuce library for node.js

Start by installing the latest Node.js version (v7.6 or later) on your system. It is very easy. You can download it from the official web site: <http://nodejs.org>. Make sure to install it fully, including npm, and add it to the system path.

¹ www.yoctopuce.com/EN/libraries.php

² www.yoctopuce.com/EN/virtualhub.php

To give it a try, go into one of the example directory (for instance `example_nodejs/Doc-Inventory`). You will see that it include an application description file (`package.json`) and a source file (`demo.js`). To download and setup the libraries needed by this example, just run:

```
npm install
```

Once done, you can start the example file using:

```
node demo.js
```

Using a local copy of the Yoctopuce library with node.js

If for some reason you need to make changes to the Yoctopuce library, you can easily configure your project to use the local copy in the `lib/` subdirectory rather than the official npm package. In order to do so, simply type the following command in your project directory:

```
npm link ../../lib
```

Using the Yoctopuce library within a browser (HTML)

For HTML examples, it is even simpler: there is nothing to install. Each example is a single HTML file that you can open in a browser to try it. In this context, loading the Yoctopuce library is no different from any standard HTML script include tag.

Using the Yoctoluce library on older JavaScript engines

If you need to run this library on older JavaScript engines, you can use Babel³ to transpile your code and the library into older JavaScript standards. To install Babel with typical settings, simply use:

```
npm instal -g babel-cli
npm instal babel-preset-env
```

You would typically ask Babel to put the transpiled files in another directory, named `compat` for instance. Your files and all files of the Yoctopuce library should be transpiled, as follow:

```
babel --presets env demo.js --out-dir compat/
babel --presets env ../../lib --out-dir compat/
```

Although this approach is based on node.js toolchain, it actually works as well for transpiling JavaScript files for use in a browser. The only thing that you cannot do so easily is transpiling JavaScript code embedded directly in an HTML page. You have to use an external script file for using EcmaScript 2017 syntax with Babel.

Babel has many smart features, such as a watch mode that will automatically refresh transpiled files whenever the source file is changed, but this is beyond the scope of this note. You will find more in Babel documentation.

Backward-compatibility with the old JavaScript library

This new library is not fully backward-compatible with the old JavaScript library, because there is no way to transparently map the old blocking API to the new asynchronous API. The method names however are the same, and old synchronous code can easily be made asynchronous just by adding the proper `await` keywords before the method calls. For instance, simply replace:

```
beaconState = module.get_beacon();
```

by

³ <http://babeljs.io>

```
beaconState = await module.get_beacon();
```

Apart from a few exceptions, most XXX_async redundant methods have been removed as well, as they would have introduced confusion on the proper way of handling asynchronous behaviors. It is however very simple to get an async method to invoke a callback upon completion, using the returned Promise object. For instance, you can replace:

```
module.get_beacon_async(callback, myContext);
```

by

```
module.get_beacon().then(function(res) { callback(myContext, module, res); });
```

In some cases, it might be desirable to get a sensor value using a method identical to the old synchronous methods (without using Promises), even if it returns a slightly outdated cached value since I/O is not possible. For this purpose, the EcmaScript library introduce new classes called *synchronous proxies*. A synchronous proxy is an object that mirrors the most recent state of the connected class, but can be read using regular synchronous function calls. For instance, instead of writing:

```
async function logInfo(module)
{
  console.log('Name: '+await module.get_logicalName());
  console.log('Beacon: '+await module.get_beacon());
}

...
logInfo(myModule);
...
```

you can use:

```
function logInfoProxy(moduleSyncProxy)
{
  console.log('Name: '+moduleProxy.get_logicalName());
  console.log('Beacon: '+moduleProxy.get_beacon());
}

logInfoSync(await myModule.get_syncProxy());
```

You can also rewrite this last asynchronous call as:

```
myModule.get_syncProxy().then(logInfoProxy);
```

7.3. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a JavaScript code snippet to use the Relay function.

```
// For Node.js, we use function require()
// For HTML, we would use <script src="...">
require('yoctolib-es2017/yocto_api.js');
require('yoctolib-es2017/yocto_relay.js');

// Get access to your device, through the VirtualHub running locally
await YAPI.RegisterHub('127.0.0.1');
var relay = YRelay.FindRelay("RELAYHI1-123456.relay1");

// Check that the module is online to handle hot-plug
if(await relay.isOnline())
{
  // Use relay.set_state()
  [...]
}
```

```
}
```

Let us look at these lines in more details.

yocto_api and yocto_relay import

These two imports provide access to functions allowing you to manage Yoctopuce modules. `yocto_api` is always needed, `yocto_relay` is necessary to manage modules containing a relay, such as Yocto-PowerRelay. Other imports can be useful in other cases, such as `YModule` which can let you enumerate any type of Yoctopuce device.

YAPI.RegisterHub

The `RegisterHub` method allows you to indicate on which machine the Yoctopuce modules are located, more precisely on which machine the VirtualHub software is running. In our case, the `127.0.0.1:4444` address indicates the local machine, port 4444 (the standard port used by Yoctopuce). You can very well modify this address, and enter the address of another machine on which the VirtualHub software is running, or of a YoctoHub. If the host cannot be reached, this function will trigger an exception.

YRelay.FindRelay

The `FindRelay` method allows you to find a relay from the serial number of the module on which it resides and from its function name. You can also use logical names, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number `RELAYHI1-123456` which you have named `"MyModule"`, and for which you have given the `relay1` function the name `"MyFunction"`. The following five calls are strictly equivalent, as long as `"MyFunction"` is defined only once.

```
relay = YRelay.FindRelay("RELAYHI1-123456.relay1")
relay = YRelay.FindRelay("RELAYHI1-123456.MaFonction")
relay = YRelay.FindRelay("MonModule.relay1")
relay = YRelay.FindRelay("MonModule.MaFonction")
relay = YRelay.FindRelay("MaFonction")
```

`YRelay.FindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `FindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `YRelay.FindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `YRelay.STATE_A` for output A, and `YRelay.STATE_B` for output B.

A real example, for Node.js

Open a command window (a terminal, a shell...) and go into the directory **example_nodejs/Doc-GettingStarted-Yocto-PowerRelay** within Yoctopuce library for JavaScript / EcmaScript 2017. In there, you will find a file named `demo.js` with the sample code below, which uses the functions explained above, but this time used with all side materials needed to make it work nicely as a small demo.

If your Yocto-PowerRelay is not connected on the host running the browser, replace in the example the address `127.0.0.1` by the IP address of the host on which the Yocto-PowerRelay is connected and where you run the VirtualHub.

```
"use strict";

require('yoctolib-es2017/yocto_api.js');
require('yoctolib-es2017/yocto_relay.js');

async function startDemo(args)
{
```

```

await YAPI.LogUnhandledPromiseRejections();
await YAPI.DisableExceptions();

// Setup the API to use the VirtualHub on local machine
let errmsg = new YErrorMsg();
if(await YAPI.RegisterHub('127.0.0.1', errmsg) !== YAPI.SUCCESS) {
  console.log('Cannot contact VirtualHub on 127.0.0.1: '+errmsg.msg);
  return;
}

// Select the relay to use
let target;
if(args[0] == "any") {
  let anyrelay = YRelay.FirstRelay();
  if (anyrelay == null) {
    console.log("No module connected (check USB cable)\n");
    process.exit(1);
  }
  let module = await anyrelay.get_module();
  target = await module.get_serialNumber();
} else {
  target = args[0];
}

// Switch relay as requested
console.log("Set output to " + args[1]);
let relay = YRelay.FindRelay(target + ".relay1");
if(await relay.isOnline()) {
  await relay.set_output(args[1] == "ON" ? YRelay.OUTPUT_ON : YRelay.OUTPUT_OFF);
} else {
  console.log("Module not connected (check identification and USB cable)\n");
}

await YAPI.FreeAPI();
}

if(process.argv.length < 4) {
  console.log("usage: node demo.js <serial_number> [ ON | OFF ]");
  console.log("      node demo.js <logical_name> [ ON | OFF ]");
  console.log("      node demo.js any [ ON | OFF ]          (use any discovered
device)");
} else {
  startDemo(process.argv.slice(process.argv.length - 2));
}

```

As explained at the beginning of this chapter, you need to have Node.js v7.6 or later installed to try this example. When done, you can type the following two commands to automatically download and install the dependencies for building this example:

```
npm install
```

You can start the sample code within Node.js using the following command, replacing the [...] by the arguments that you want to pass to the demo code:

```
node demo.js [...]
```

Same example, but this time running in a browser

If you want to see how to use the library within a browser rather than with Node.js, switch to the directory **example_html/Doc-GettingStarted-Yocto-PowerRelay**. You will find there a single HTML file, with a JavaScript section similar to the code above, but with a few changes since it has to interact through an HTML page rather than through the JavaScript console.

```

<!DOCTYPE html>
<html>
<head>
  <meta charset="UTF-8">
  <title>Hello World</title>
  <script src="../../lib/yocto_api.js"></script>
  <script src="../../lib/yocto_relay.js"></script>
</script>

```

```

let relay;

async function startDemo()
{
    await YAPI.LogUnhandledPromiseRejections();
    await YAPI.DisableExceptions();

    // Setup the API to use the VirtualHub on local machine
    let errmsg = new YErrorMsg();
    if(await YAPI.RegisterHub('ws://127.0.0.1', errmsg) != YAPI.SUCCESS) {
        alert('Cannot contact VirtualHub on 127.0.0.1: '+errmsg.msg);
    }
    refresh();
}

async function refresh()
{
    let serial = document.getElementById('serial').value;
    if(serial == '') {
        // by default use any connected module suitable for the demo
        let anyRelay = YRelay.FirstRelay();
        if(anyRelay) {
            let module = await anyRelay.module();
            serial = await module.get_serialNumber();
            document.getElementById('serial').value = serial;
        }
    }
    relay = YRelay.FindRelay(serial+".relay1");
    if(await relay.isOnline()) {
        document.getElementById('msg').value = '';
    } else {
        document.getElementById('msg').value = 'Module not connected';
    }
    setTimeout(refresh, 500);
}

window.sw = function(state)
{
    relay.set_output(state ? YRelay.OUTPUT_ON : YRelay.OUTPUT_OFF);
};

startDemo();
</script>
</head>
<body>
Module to use: <input id='serial'>
<input id='msg' style='color:red;border:none;' readonly><br>
Relay <a href='javascript:sw(0);' >OFF</a> / <a href='javascript:sw(1);' >ON</a><br>
</body>
</html>

```

No installation is needed to run this example, all you have to do is open the HTML file using a web browser,

7.4. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```

"use strict";

require('yoctolib-es2017/yocto_api.js');

async function startDemo(args)
{
    await YAPI.LogUnhandledPromiseRejections();

    // Setup the API to use the VirtualHub on local machine
    let errmsg = new YErrorMsg();
    if(await YAPI.RegisterHub('127.0.0.1', errmsg) != YAPI.SUCCESS) {
        console.log('Cannot contact VirtualHub on 127.0.0.1: '+errmsg.msg);
        return;
    }
}

```

```
// Select the relay to use
let module = YModule.FindModule(args[0]);
if(await module.isOnline()) {
    if(args.length > 1) {
        if(args[1] == 'ON') {
            await module.set_beacon(YModule.BEACON_ON);
        } else {
            await module.set_beacon(YModule.BEACON_OFF);
        }
    }
    console.log('serial:      '+await module.get_serialNumber());
    console.log('logical name: '+await module.get_logicalName());
    console.log('luminosity:  '+await module.get_luminosity()+'%');
    console.log('beacon:      '+ (await module.get_beacon() == YModule.BEACON_ON
? 'ON': 'OFF'));
    console.log('upTime:      '+parseInt(await module.get_upTime()/1000)+' sec');
    console.log('USB current:  '+await module.get_usbCurrent()+' mA');
    console.log('logs:');
    console.log(await module.get_lastLogs());
} else {
    console.log("Module not connected (check identification and USB cable)\n");
}
await YAPI.FreeAPI();
}

if(process.argv.length < 2) {
    console.log("usage: node demo.js <serial or logicalname> [ ON | OFF ]");
} else {
    startDemo(process.argv.slice(2));
}
}
```

Each property `xxx` of the module can be read thanks to a method of type `get_xxxx()`, and properties which are not read-only can be modified with the help of the `set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```
"use strict";

require('yoctolib-es2017/yocto_api.js');

async function startDemo(args)
{
    await YAPI.LogUnhandledPromiseRejections();

    // Setup the API to use the VirtualHub on local machine
    let errmsg = new YErrorMsg();
    if(await YAPI.RegisterHub('127.0.0.1', errmsg) != YAPI.SUCCESS) {
        console.log('Cannot contact VirtualHub on 127.0.0.1: '+errmsg.msg);
        return;
    }

    // Select the relay to use
    let module = YModule.FindModule(args[0]);
    if(await module.isOnline()) {
        if(args.length > 1) {
            let newname = args[1];
            if (!await YAPI.CheckLogicalName(newname)) {
                console.log("Invalid name (" + newname + ")");
                process.exit(1);
            }
            await module.set_logicalName(newname);
            await module.saveToFlash();
        }
        console.log('Current name: '+await module.get_logicalName());
    } else {

```

```

        console.log("Module not connected (check identification and USB cable)\n");
    }
    await YAPI.FreeAPI();
}

if(process.argv.length < 2) {
    console.log("usage: node demo.js <serial> [newLogicalName]");
} else {
    startDemo(process.argv.slice(2));
}

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `YModule.FirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not null. Below a short example listing the connected modules.

```

"use strict";

require('yoctolib-es2017/yocto_api.js');

async function startDemo()
{
    await YAPI.LogUnhandledPromiseRejections();
    await YAPI.DisableExceptions();

    // Setup the API to use the VirtualHub on local machine
    let errmsg = new YErrorMsg();
    if (await YAPI.RegisterHub('127.0.0.1', errmsg) !== YAPI.SUCCESS) {
        console.log('Cannot contact VirtualHub on 127.0.0.1');
        return;
    }
    refresh();
}

async function refresh()
{
    try {
        let errmsg = new YErrorMsg();
        await YAPI.UpdateDeviceList(errmsg);

        let module = YModule.FirstModule();
        while(module) {
            let line = await module.get_serialNumber();
            line += '(' + (await module.get_productName()) + ')';
            console.log(line);
            module = module.nextModule();
        }
        setTimeout(refresh, 500);
    } catch(e) {
        console.log(e);
    }
}

try {
    startDemo();
} catch(e) {
    console.log(e);
}

```

7.5. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

8. Using Yocto-PowerRelay with PHP

PHP is, like Javascript, an atypical language when interfacing with hardware is at stakes. Nevertheless, using PHP with Yoctopuce modules provides you with the opportunity to very easily create web sites which are able to interact with their physical environment, and this is not available to every web server. This technique has a direct application in home automation: a few Yoctopuce modules, a PHP server, and you can interact with your home from anywhere on the planet, as long as you have an internet connection.

PHP is one of those languages which do not allow you to directly access the hardware layers of your computer. Therefore you need to run a virtual hub on the machine on which your modules are connected.

To start your tests with PHP, you need a PHP 5.3 (or more) server¹, preferably locally on you machine. If you wish to use the PHP server of your internet provider, it is possible, but you will probably need to configure your ADSL router for it to accept and forward TCP request on the 4444 port.

8.1. Getting ready

Go to the Yoctopuce web site and download the following items:

- The PHP programming library²
- The VirtualHub software³ for Windows, Mac OS X, or Linux, depending on your OS

Decompress the library files in a folder of your choice accessible to your web server, connect your modules, run the VirtualHub software, and you are ready to start your first tests. You do not need to install any driver.

8.2. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a PHP code snippet to use the Relay function.

```
include('yocto_api.php');  
include('yocto_relay.php');
```

¹ A couple of free PHP servers: easyPHP for Windows, MAMP for Mac OS X.

² www.yoctopuce.com/EN/libraries.php

³ www.yoctopuce.com/EN/virtualhub.php

```
// Get access to your device, through the VirtualHub running locally
yRegisterHub('http://127.0.0.1:4444/', $errmsg);
$relay = yFindRelay("RELAYHI1-123456.relay1");

// Check that the module is online to handle hot-plug
if($relay->isOnline())
{
    // Use relay->set_state(), ...
}
```

Let's look at these lines in more details.

yocto_api.php and yocto_relay.php

These two PHP includes provides access to the functions allowing you to manage Yoctopuce modules. `yocto_api.php` must always be included, `yocto_relay.php` is necessary to manage modules containing a relay, such as Yocto-PowerRelay.

yRegisterHub

The `yRegisterHub` function allows you to indicate on which machine the Yoctopuce modules are located, more precisely on which machine the VirtualHub software is running. In our case, the 127.0.0.1:4444 address indicates the local machine, port 4444 (the standard port used by Yoctopuce). You can very well modify this address, and enter the address of another machine on which the VirtualHub software is running.

yFindRelay

The `yFindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number *RELAYHI1-123456* which you have named "MyModule", and for which you have given the *relay1* function the name "MyFunction". The following five calls are strictly equivalent, as long as "MyFunction" is defined only once.

```
$relay = yFindRelay("RELAYHI1-123456.relay1");
$relay = yFindRelay("RELAYHI1-123456.MyFunction");
$relay = yFindRelay("MyModule.relay1");
$relay = yFindRelay("MyModule.MyFunction");
$relay = yFindRelay("MyFunction");
```

`yFindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `yFindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the objet returned by `yFindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `Y_STATE_A` for output A, and `Y_STATE_B` for output B.

A real example

Open your preferred text editor⁴, copy the code sample below, save it with the Yoctopuce library files in a location which is accessible to you web server, then use your preferred web browser to access this page. The code is also provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library.

In this example, you will recognize the functions explained above, but this time used with all side materials needed to make it work nicely as a small demo.

⁴ If you do not have a text editor, use Notepad rather than Microsoft Word.

```

<HTML>
<HEAD>
  <TITLE>Hello World</TITLE>
</HEAD>
<BODY>
  <FORM method='get'>
  <?php
    include('yocto_api.php');
    include('yocto_relay.php');

    // Use explicit error handling rather than exceptions
    yDisableExceptions();

    // Setup the API to use the VirtualHub on local machine
    if(yRegisterHub('http://127.0.0.1:4444/', $errmsg) != YAPI_SUCCESS) {
        die("Cannot contact VirtualHub on 127.0.0.1");
    }

    @$serial = $_GET['serial'];
    if ($serial != '') {
        // Check if a specified module is available online
        $relay = yFindRelay("$serial.relay1");
        if (!$relay->isOnline()) {
            die("Module not connected (check serial and USB cable)");
        }
    } else {
        // or use any connected module suitable for the demo
        $relay = yFirstRelay();
        if(is_null($relay)) {
            die("No module connected (check USB cable)");
        } else {
            $serial = $relay->module()->get_serialnumber();
        }
    }
    Print("Module to use: <input name='serial' value='$serial'><br>");

    // Drive the selected module
    if (isset($_GET['state'])) {
        $state = $_GET['state'];
        if ($state=='A') $relay->set_state(Y_STATE_A);
        if ($state=='B') $relay->set_state(Y_STATE_B);
    }
    yFreeAPI();
  ?>
  <input type='radio' name='state' value='A'>Output A
  <input type='radio' name='state' value='B'>Output B
  <br><input type='submit'>
  </FORM>
</BODY>
</HTML>

```

8.3. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```

<HTML>
<HEAD>
  <TITLE>Module Control</TITLE>
</HEAD>
<BODY>
  <FORM method='get'>
  <?php
    include('yocto_api.php');

    // Use explicit error handling rather than exceptions
    yDisableExceptions();

    // Setup the API to use the VirtualHub on local machine
    if(yRegisterHub('http://127.0.0.1:4444/', $errmsg) != YAPI_SUCCESS) {
        die("Cannot contact VirtualHub on 127.0.0.1 : ".$errmsg);
    }
  ?>

```

```

@$serial = $_GET['serial'];
if ($serial != '') {
    // Check if a specified module is available online
    $module = yFindModule("$serial");
    if (!$module->isOnline()) {
        die("Module not connected (check serial and USB cable)");
    }
} else {
    // or use any connected module suitable for the demo
    $module = yFirstModule();
    if ($module) { // skip VirtualHub
        $module = $module->nextModule();
    }
    if (is_null($module)) {
        die("No module connected (check USB cable)");
    } else {
        $serial = $module->get_serialnumber();
    }
}
Print("Module to use: <input name='serial' value='$serial'><br>");

if (isset($_GET['beacon'])) {
    if ($_GET['beacon']=='ON')
        $module->set_beacon(Y_BEACON_ON);
    else
        $module->set_beacon(Y_BEACON_OFF);
}
printf('serial: %s<br>', $module->get_serialNumber());
printf('logical name: %s<br>', $module->get_logicalName());
printf('luminosity: %s<br>', $module->get_luminosity());
print('beacon: ');
if ($module->get_beacon() == Y_BEACON_ON) {
    printf("<input type='radio' name='beacon' value='ON' checked>ON ");
    printf("<input type='radio' name='beacon' value='OFF'>OFF<br>");
} else {
    printf("<input type='radio' name='beacon' value='ON'>ON ");
    printf("<input type='radio' name='beacon' value='OFF' checked>OFF<br>");
}
printf('upTime: %s sec<br>', intval($module->get_upTime()/1000));
printf('USB current: %smA<br>', $module->get_usbCurrent());
printf('logs:<br><pre>%s</pre>', $module->get_lastLogs());
yFreeAPI();
?>
<input type='submit' value='refresh'>
</FORM>
</BODY>
</HTML>

```

Each property `xxx` of the module can be read thanks to a method of type `get_xxxx()`, and properties which are not read-only can be modified with the help of the `set_xxxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

<HTML>
<HEAD>
<TITLE>save settings</TITLE>
<BODY>
<FORM method='get'>
<?php
    include('yocto_api.php');

    // Use explicit error handling rather than exceptions
    yDisableExceptions();

    // Setup the API to use the VirtualHub on local machine

```

```

if(yRegisterHub('http://127.0.0.1:4444/', $errmsg) != YAPI_SUCCESS) {
    die("Cannot contact VirtualHub on 127.0.0.1");
}

@$serial = $_GET['serial'];
if ($serial != '') {
    // Check if a specified module is available online
    $module = yFindModule("$serial");
    if (!$module->isOnline()) {
        die("Module not connected (check serial and USB cable)");
    }
} else {
    // or use any connected module suitable for the demo
    $module = yFirstModule();
    if($module) { // skip VirtualHub
        $module = $module->nextModule();
    }
    if(is_null($module)) {
        die("No module connected (check USB cable)");
    } else {
        $serial = $module->get_serialnumber();
    }
}
Print("Module to use: <input name='serial' value='$serial'><br>");

if (isset($_GET['newname'])){
    $newname = $_GET['newname'];
    if (!yCheckLogicalName($newname))
        die('Invalid name');
    $module->set_logicalName($newname);
    $module->saveToFlash();
}
printf("Current name: %s<br>", $module->get_logicalName());
print("New name: <input name='newname' value='' maxlength=19><br>");
yFreeAPI();
?>
<input type='submit'>
</FORM>
</BODY>
</HTML>

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `NULL`. Below a short example listing the connected modules.

```

<HTML>
<HEAD>
<TITLE>inventory</TITLE>
</HEAD>
<BODY>
<H1>Device list</H1>
<TT>
<?php
    include('yocto_api.php');
    yRegisterHub("http://127.0.0.1:4444/");
    $module = yFirstModule();
    while (!is_null($module)) {
        printf("%s (%s)<br>", $module->get_serialNumber(),
            $module->get_productName());
        $module=$module->nextModule();
    }
    yFreeAPI();
?>
</TT>
</BODY>

```

</HTML>

8.4. HTTP callback API and NAT filters

The PHP library is able to work in a specific mode called *HTTP callback Yocto-API*. With this mode, you can control Yoctopuce devices installed behind a NAT filter, such as a DSL router for example, and this without needing to open a port. The typical application is to control Yoctopuce devices, located on a private network, from a public web site.

The NAT filter: advantages and disadvantages

A DSL router which translates network addresses (NAT) works somewhat like a private phone switchboard (a PBX): internal extensions can call each other and call the outside; but seen from the outside, there is only one official phone number, that of the switchboard itself. You cannot reach the internal extensions from the outside.

Typical DSL configuration: LAN machines are isolated from the outside by the DSL router

Transposed to the network, we have the following: appliances connected to your home automation network can communicate with one another using a local IP address (of the 192.168.xxx.yyy type), and contact Internet servers through their public address. However, seen from the outside, you have only one official IP address, assigned to the DSL router only, and you cannot reach your network appliances directly from the outside. It is rather restrictive, but it is a relatively efficient protection against intrusions.

Responses from request from LAN machines are routed.

But requests from the outside are blocked.

Seeing Internet without being seen provides an enormous security advantage. However, this signifies that you cannot, a priori, set up your own web server at home to control a home automation installation from the outside. A solution to this problem, advised by numerous home automation system dealers, consists in providing outside visibility to your home automation server itself, by adding a routing rule in the NAT configuration of the DSL router. The issue of this solution is that it exposes the home automation server to external attacks.

The HTTP callback API solves this issue without having to modify the DSL router configuration. The module control script is located on an external site, and it is the *VirtualHub* which is in charge of calling it a regular intervals.

The HTTP callback API uses the VirtualHub which initiates the requests.

Configuration

The callback API thus uses the *VirtualHub* as a gateway. All the communications are initiated by the *VirtualHub*. They are thus outgoing communications and therefore perfectly authorized by the DSL router.

You must configure the *VirtualHub* so that it calls the PHP script on a regular basis. To do so:

1. Launch a *VirtualHub*
2. Access its interface, usually 127.0.0.1:4444
3. Click on the **configure** button of the line corresponding to the *VirtualHub* itself
4. Click on the **edit** button of the **Outgoing callbacks** section

Serial	Logical Name	Description	Action
VIRIHUB0-7d1a86fb0	VirtualHub	VirtualHub	configure view log file
RELAYHI1-00055	Yocto-PowerRelay	Yocto-PowerRelay	configure view log file beacon
TMPSENS1-05E7F	Yocto-Temperature	Yocto-Temperature	configure view log file beacon

Click on the "configure" button on the first line

Edit parameters for VIRTHUB0-7d1a86fb09, and click on the **Save** button.

Serial #: VIRTHUB0-7d1a86fb09
 Product name: VirtualHub
 Software version: 10789
 Logical name:

Incoming connections

Authentication to read information from the devices: NO
 Authentication to make changes to the devices: NO

Outgoing callbacks

Callback URL: octoHub
 Delay between callbacks: min: 3 [s] max: 600 [s]

Click on the "edit" button of the "Outgoing callbacks" section

This VirtualHub can post the advertised values of all devices on a specific URL on a regular basis. If you wish to use this feature, choose the callback type follow the steps below carefully.

1. Specify the Type of callback you want to use:

Yoctopuce devices can be controlled through remote PHP scripts. That Yocto-API callback protocol is designed so it can pass through NAT filters without opening ports. See your device user manual, *PHP programming* section for more details.

2. Specify the URL to use for reporting values. *HTTPS protocol is not yet supported.*
 Callback URL:

3. If your callback requires authentication, enter credentials here. Digest authentication is recommended, but Basic authentication works as well.
 Username:
 Password:

4. Setup the desired frequency of notifications:
 No less than seconds between two notification
 But notify after seconds in any case

5. Press on the **Test** button to check your parameters.
 6. When everything works, press on the **OK** button.

And select "Yocto-API callback".

You then only need to define the URL of the PHP script and, if need be, the user name and password to access this URL. Supported authentication methods are *basic* and *digest*. The second method is safer than the first one because it does not allow transfer of the password on the network.

Usage

From the programmer standpoint, the only difference is at the level of the `yRegisterHub` function call. Instead of using an IP address, you must use the `callback` string (or `http://callback` which is equivalent).

```
include("yocto_api.php");
yRegisterHub("callback");
```

The remainder of the code stays strictly identical. On the *VirtualHub* interface, at the bottom of the configuration window for the HTTP callback API, there is a button allowing you to test the call to the PHP script.

Be aware that the PHP script controlling the modules remotely through the HTTP callback API can be called only by the *VirtualHub*. Indeed, it requires the information posted by the *VirtualHub* to function. To code a web site which controls Yoctopuce modules interactively, you must create a user interface which stores in a file or in a database the actions to be performed on the Yoctopuce modules. These actions are then read and run by the control script.

Common issues

For the HTTP callback API to work, the PHP option `allow_url_fopen` must be set. Some web site hosts do not set it by default. The problem then manifests itself with the following error:

```
error: URL file-access is disabled in the server configuration
```

To set this option, you must create, in the repertory where the control PHP script is located, an `.htaccess` file containing the following line:

```
php_flag "allow_url_fopen" "On"
```

Depending on the security policies of the host, it is sometimes impossible to authorize this option at the root of the web site, or even to install PHP scripts receiving data from a POST HTTP. In this case, place the PHP script in a subdirectory.

Limitations

This method that allows you to go through NAT filters cheaply has nevertheless a price. Communications being initiated by the *VirtualHub* at a more or less regular interval, reaction time to an event is clearly longer than if the Yoctopuce modules were driven directly. You can configure the reaction time in the specific window of the *VirtualHub*, but it is at least of a few seconds in the best case.

The *HTTP callback Yocto-API* mode is currently available in PHP, EcmaScript (Node.JS) and Java only.

8.5. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing

your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

9. Using Yocto-PowerRelay with C++

C++ is not the simplest language to master. However, if you take care to limit yourself to its essential functionalities, this language can very well be used for short programs quickly coded, and it has the advantage of being easily ported from one operating system to another. Under Windows, all the examples and the project models are tested with Microsoft Visual Studio 2010 Express, freely available on the Microsoft web site¹. Under Mac OS X, all the examples and project models are tested with XCode 4, available on the App Store. Moreover, under Mac OS X and under Linux, you can compile the examples using a command line with GCC using the provided `GNUmakefile`. In the same manner under Windows, a `Makefile` allows you to compile examples using a command line, fully knowing the compilation and linking arguments.

Yoctopuce C++ libraries² are integrally provided as source files. A section of the low-level library is written in pure C, but you should not need to interact directly with it: everything was done to ensure the simplest possible interaction from C++. The library is naturally also available as binary files, so that you can link it directly if you prefer.

You will soon notice that the C++ API defines many functions which return objects. You do not need to deallocate these objects yourself, the API does it automatically at the end of the application.

In order to keep them simple, all the examples provided in this documentation are console applications. Naturally, the libraries function in a strictly identical manner if you integrate them in an application with a graphical interface. You will find in the last section of this chapter all the information needed to create a wholly new project linked with the Yoctopuce libraries.

9.1. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a C++ code snippet to use the Relay function.

```
#include "yocto_api.h"
#include "yocto_relay.h"

[...]
String errmsg;
YRelay *relay;

// Get access to your device, connected locally on USB for instance
yRegisterHub("usb", errmsg);
relay = yFindRelay("RELAYHI1-123456.relay1");
```

¹ <http://www.microsoft.com/visualstudio/en-us/products/2010-editions/visual-cpp-express>

² www.yoctopuce.com/EN/libraries.php

```
// Hot-plug is easy: just check that the device is online
if (relay->isOnline())
{
    // Use relay->set_state(), ...
}
```

Let's look at these lines in more details.

yocto_api.h et yocto_relay.h

These two include files provide access to the functions allowing you to manage Yoctopuce modules. `yocto_api.h` must always be used, `yocto_relay.h` is necessary to manage modules containing a relay, such as Yocto-PowerRelay.

yRegisterHub

The `yRegisterHub` function initializes the Yoctopuce API and indicates where the modules should be looked for. When used with the parameter `"usb"`, it will use the modules locally connected to the computer running the library. If the initialization does not succeed, this function returns a value different from `YAPI_SUCCESS` and `errmsg` contains the error message.

yFindRelay

The `yFindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number `RELAYHI1-123456` which you have named `"MyModule"`, and for which you have given the `relay1` function the name `"MyFunction"`. The following five calls are strictly equivalent, as long as `"MyFunction"` is defined only once.

```
YRelay *relay = yFindRelay("RELAYHI1-123456.relay1");
YRelay *relay = yFindRelay("RELAYHI1-123456.MyFunction");
YRelay *relay = yFindRelay("MyModule.relay1");
YRelay *relay = yFindRelay("MyModule.MyFunction");
YRelay *relay = yFindRelay("MyFunction");
```

`yFindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `yFindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `yFindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `Y_STATE_A` for output A, and `Y_STATE_B` for output B.

A real example

Launch your C++ environment and open the corresponding sample project provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library. If you prefer to work with your favorite text editor, open the file `main.cpp`, and type `make` to build the example when you are done.

In this example, you will recognize the functions explained above, but this time used with all side materials needed to make it work nicely as a small demo.

```
#include "yocto_api.h"
#include "yocto_relay.h"
#include <iostream>
#include <ctype.h>
#include <stdlib.h>

using namespace std;
```

```

static void usage(void)
{
    cout << "usage: demo <serial_number> [ A | B ]" << endl;
    cout << "      demo <logical_name> [ A | B ]" << endl;
    cout << "      demo any [ A | B ]          (use any discovered device)" << endl;
    u64 now = yGetTickCount();
    while (yGetTickCount() - now < 3000) {
        // wait 3 sec to show the message
    }
    exit(1);
}

int main(int argc, const char * argv[])
{
    string  errmsg;
    string  target;
    YRelay  *relay;
    char    state;

    if (argc < 3) {
        usage();
    }
    target = (string) argv[1];
    state = toupper(argv[2][0]);

    // Setup the API to use local USB devices
    if (yRegisterHub("usb", errmsg) != YAPI_SUCCESS) {
        cerr << "RegisterHub error: " << errmsg << endl;
        return 1;
    }

    if (target == "any") {
        relay = yFirstRelay();
        if (relay == NULL) {
            cout << "No module connected (check USB cable)" << endl;
            return 1;
        }
    }
    else {
        relay = yFindRelay(target + ".relay1");
    }

    if (relay->isOnline()) {
        relay->set_state(state == 'A' ? Y_STATE_A : Y_STATE_B);
    }
    else {
        cout << "Module not connected (check identification and USB cable)" << endl;
    }
    yFreeAPI();

    return 0;
}

```

9.2. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```

#include <iostream>
#include <stdlib.h>

#include "yocto_api.h"

using namespace std;

static void usage(const char *exe)
{
    cout << "usage: " << exe << " <serial or logical name> [ON/OFF]" << endl;
    exit(1);
}

int main(int argc, const char * argv[])
{

```

```

string      errmsg;

// Setup the API to use local USB devices
if(yRegisterHub("usb", errmsg) != YAPI_SUCCESS) {
    cerr << "RegisterHub error: " << errmsg << endl;
    return 1;
}

if(argc < 2)
    usage(argv[0]);

YModule *module = yFindModule(argv[1]); // use serial or logical name

if (module->isOnline()) {
    if (argc > 2) {
        if (string(argv[2]) == "ON")
            module->set_beacon(Y_BEACON_ON);
        else
            module->set_beacon(Y_BEACON_OFF);
    }
    cout << "serial:      " << module->get_serialNumber() << endl;
    cout << "logical name: " << module->get_logicalName() << endl;
    cout << "luminosity:  " << module->get_luminosity() << endl;
    cout << "beacon:      ";
    if (module->get_beacon() == Y_BEACON_ON)
        cout << "ON" << endl;
    else
        cout << "OFF" << endl;
    cout << "upTime:      " << module->get_upTime() / 1000 << " sec" << endl;
    cout << "USB current: " << module->get_usbCurrent() << " mA" << endl;
    cout << "Logs:" << endl << module->get_lastLogs() << endl;
} else {
    cout << argv[1] << " not connected (check identification and USB cable)"
        << endl;
}
yFreeAPI();
return 0;
}

```

Each property `xxx` of the module can be read thanks to a method of type `get_xxxx()`, and properties which are not read-only can be modified with the help of the `set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

#include <iostream>
#include <stdlib.h>

#include "yocto_api.h"

using namespace std;

static void usage(const char *exe)
{
    cerr << "usage: " << exe << " <serial> <newLogicalName>" << endl;
    exit(1);
}

int main(int argc, const char * argv[])
{
    string      errmsg;

    // Setup the API to use local USB devices
    if(yRegisterHub("usb", errmsg) != YAPI_SUCCESS) {
        cerr << "RegisterHub error: " << errmsg << endl;
        return 1;
    }
}

```

```

}

if(argc < 2)
    usage(argv[0]);

YModule *module = yFindModule(argv[1]); // use serial or logical name

if (module->isOnline()) {
    if (argc >= 3) {
        string newname = argv[2];
        if (!yCheckLogicalName(newname)) {
            cerr << "Invalid name (" << newname << ")" << endl;
            usage(argv[0]);
        }
        module->set_logicalName(newname);
        module->saveToFlash();
    }
    cout << "Current name: " << module->get_logicalName() << endl;
} else {
    cout << argv[1] << " not connected (check identification and USB cable)"
        << endl;
}

yFreeAPI();
return 0;
}

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `NULL`. Below a short example listing the connected modules.

```

#include <iostream>

#include "yocto_api.h"

using namespace std;

int main(int argc, const char * argv[])
{
    string      errmsg;

    // Setup the API to use local USB devices
    if(YAPI::RegisterHub("usb", errmsg) != YAPI_SUCCESS) {
        cerr << "RegisterHub error:" << errmsg << endl;
        return 1;
    }

    cout << "Device list: " << endl;

    YModule *module = YModule::FirstModule();
    while (module != NULL) {
        cout << module->get_serialNumber() << " ";
        cout << module->get_productName() << endl;
        module = module->nextModule();
    }
    yFreeAPI();
    return 0;
}

```

9.3. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `getState()` method returns a `Y_STATE_INVALID` value, a `getCurrentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

9.4. Integration variants for the C++ Yoctopuce library

Depending on your needs and on your preferences, you can integrate the library into your projects in several distinct manners. This section explains how to implement the different options.

Integration in source format

Integrating all the sources of the library into your projects has several advantages:

- It guaranties the respect of the compilation conventions of your project (32/64 bits, inclusion of debugging symbols, unicode or ASCII characters, etc.);
- It facilitates debugging if you are looking for the cause of a problem linked to the Yoctopuce library;
- It reduces the dependencies on third party components, for example in the case where you would need to recompile this project for another architecture in many years;
- It does not require the installation of a dynamic library specific to Yoctopuce on the final system, everything is in the executable.

To integrate the source code, the easiest way is to simply include the `Sources` directory of your Yoctopuce library into your **IncludePath**, and to add all the files of this directory (including the sub-directory `yapi`) to your project.

For your project to build correctly, you need to link with your project the prerequisite system libraries, that is:

- For Windows: the libraries are added automatically
- For Mac OS X: **IOKit.framework** and **CoreFoundation.framework**
- For Linux: **libm**, **libpthread**, **libusb1.0**, and **libstdc++**

Integration as a static library

Integration of the Yoctopuce library as a static library is a simpler manner to build a small executable which uses Yoctopuce modules. You can quickly compile the program with a single command. You do not need to install a dynamic library specific to Yoctopuce, everything is in the executable.

To integrate the static Yoctopuce library to your project, you must include the `Sources` directory of the Yoctopuce library into your **IncludePath**, and add the sub-directory `Binaries/...` corresponding to your operating system into your **libPath**.

Then, for you project to build correctly, you need to link with your project the Yoctopuce library and the prerequisite system libraries:

- For Windows: **yocto-static.lib**
- For Mac OS X: **libyocto-static.a**, **IOKit.framework**, and **CoreFoundation.framework**
- For Linux: **libyocto-static.a**, **libm**, **libpthread**, **libusb1.0**, and **libstdc++**.

Note, under Linux, if you wish to compile in command line with GCC, it is generally advisable to link system libraries as dynamic libraries, rather than as static ones. To mix static and dynamic libraries on the same command line, you must pass the following arguments:

```
gcc (...) -Wl,-Bstatic -lyocto-static -Wl,-Bdynamic -lm -lpthread -lusb-1.0 -lstdc++
```

Integration as a dynamic library

Integration of the Yoctopuce library as a dynamic library allows you to produce an executable smaller than with the two previous methods, and to possibly update this library, if a patch reveals itself necessary, without needing to recompile the source code of the application. On the other hand, it is an integration mode which systematically requires you to copy the dynamic library on the target machine where the application will run (**yocto.dll** for Windows, **libyocto.so.1.0.1** for Mac OS X and Linux).

To integrate the dynamic Yoctopuce library to your project, you must include the `Sources` directory of the Yoctopuce library into your **IncludePath**, and add the sub-directory `Binaries/...` corresponding to your operating system into your **LibPath**.

Then, for you project to build correctly, you need to link with your project the dynamic Yoctopuce library and the prerequisite system libraries:

- For Windows: **yocto.lib**
- For Mac OS X: **libyocto**, **IOKit.framework**, and **CoreFoundation.framework**
- For Linux: **libyocto**, **libm**, **libpthread**, **libusb1.0**, and **libstdc++**.

With GCC, the command line to compile is simply:

```
gcc (...) -lyocto -lm -lpthread -lusb-1.0 -lstdc++
```

10. Using Yocto-PowerRelay with Objective-C

Objective-C is language of choice for programming on Mac OS X, due to its integration with the Cocoa framework. In order to use the Objective-C library, you need XCode version 4.2 (earlier versions will not work), available freely when you run Lion. If you are still under Snow Leopard, you need to be registered as Apple developer to be able to download XCode 4.2. The Yoctopuce library is ARC compatible. You can therefore implement your projects either using the traditional *retain / release* method, or using the *Automatic Reference Counting*.

Yoctopuce Objective-C libraries¹ are integrally provided as source files. A section of the low-level library is written in pure C, but you should not need to interact directly with it: everything was done to ensure the simplest possible interaction from Objective-C.

You will soon notice that the Objective-C API defines many functions which return objects. You do not need to deallocate these objects yourself, the API does it automatically at the end of the application.

In order to keep them simple, all the examples provided in this documentation are console applications. Naturally, the libraries function in a strictly identical manner if you integrate them in an application with a graphical interface. You can find on Yoctopuce blog a detailed example² with video shots showing how to integrate the library into your projects.

10.1. Control of the Relay function

Launch Xcode 4.2 and open the corresponding sample project provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library.

```
#import <Foundation/Foundation.h>
#import "yocto_api.h"
#import "yocto_relay.h"

static void usage(void)
{
    NSLog(@"usage: demo <serial_number> [ A | B ]");
    NSLog(@"          demo <logical_name> [ A | B ]");
    NSLog(@"          demo any [ A | B ]          (use any discovered device)");
    exit(1);
}

int main(int argc, const char * argv[])
{
```

¹ www.yoctopuce.com/EN/libraries.php

² www.yoctopuce.com/EN/article/new-objective-c-library-for-mac-os-x

```

NSError *error;

if (argc < 3) {
    usage();
}

@autoreleasepool {
    // Setup the API to use local USB devices
    if([YAPI RegisterHub:@"usb": &error] != YAPI_SUCCESS) {
        NSLog(@"RegisterHub error: %@", [error localizedDescription]);
        return 1;
    }
    NSString *target = [NSString stringWithUTF8String:argv[1]];
    NSString *state = [NSString stringWithUTF8String:argv[2]];
    YRelay *relay;

    if ([target isEqualToString:@"any"]) {
        relay = [YRelay FirstRelay];
        if (relay == NULL) {
            NSLog(@"No module connected (check USB cable)");
            return 1;
        }
    } else {
        relay = [YRelay FindRelay:target];
    }
    if ([relay isOnline]) {
        if ([state isEqualToString:@"A"])
            [relay set_state:Y_STATE_A];
        else
            [relay set_state:Y_STATE_B];
    } else {
        NSLog(@"Module not connected (check identification and USB cable)\n");
    }
    [YAPI FreeAPI];
}
return 0;
}

```

There are only a few really important lines in this example. We will look at them in details.

yocto_api.h et yocto_relay.h

These two import files provide access to the functions allowing you to manage Yoctopuce modules. `yocto_api.h` must always be used, `yocto_relay.h` is necessary to manage modules containing a relay, such as Yocto-PowerRelay.

[YAPI RegisterHub]

The `[YAPI RegisterHub]` function initializes the Yoctopuce API and indicates where the modules should be looked for. When used with the parameter `@"usb"`, it will use the modules locally connected to the computer running the library. If the initialization does not succeed, this function returns a value different from `YAPI_SUCCESS` and `errmsg` contains the error message.

[Relay FindRelay]

The `[Relay FindRelay]` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number *RELAYHI1-123456* which you have named "MyModule", and for which you have given the *relay1* function the name "MyFunction". The following five calls are strictly equivalent, as long as "MyFunction" is defined only once.

```

YRelay *relay = [Relay FindRelay:@"RELAYHI1-123456.relay1"];
YRelay *relay = [Relay FindRelay:@"RELAYHI1-123456.MyFunction"];
YRelay *relay = [Relay FindRelay:@"MyModule.relay1"];
YRelay *relay = [Relay FindRelay:@"MyModule.MyFunction"];
YRelay *relay = [Relay FindRelay:@"MyFunction"];

```

`[Relay FindRelay]` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline` method of the object returned by `[Relay FindRelay]` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `YRelay.FindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `YRelay.STATE_A` for output A, and `YRelay.STATE_B` for output B.

10.2. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```
#import <Foundation/Foundation.h>
#import "yocto_api.h"

static void usage(const char *exe)
{
    NSLog(@"usage: %s <serial or logical name> [ON/OFF]\n", exe);
    exit(1);
}

int main (int argc, const char * argv[])
{
    NSError *error;

    @autoreleasepool {
        // Setup the API to use local USB devices
        if([YAPI RegisterHub:@"usb": &error] != YAPI_SUCCESS) {
            NSLog(@"RegisterHub error: %@", [error localizedDescription]);
            return 1;
        }
        if(argc < 2)
            usage(argv[0]);
        NSString *serial_or_name = [NSString stringWithUTF8String:argv[1]];
        // use serial or logical name
        YModule *module = [YModule FindModule:serial_or_name];
        if ([module isOnline]) {
            if (argc > 2) {
                if (strcmp(argv[2], "ON") == 0)
                    [module setBeacon:Y_BEACON_ON];
                else
                    [module setBeacon:Y_BEACON_OFF];
            }
            NSLog(@"serial:      %@\n", [module serialNumber]);
            NSLog(@"logical name: %@\n", [module logicalName]);
            NSLog(@"luminosity:   %d\n", [module luminosity]);
            NSLog(@"beacon:      ");
            if ([module beacon] == Y_BEACON_ON)
                NSLog(@"ON\n");
            else
                NSLog(@"OFF\n");
            NSLog(@"upTime:      %ld sec\n", [module upTime] / 1000);
            NSLog(@"USB current: %d mA\n", [module usbCurrent]);
            NSLog(@"logs:       %@\n", [module get_lastLogs]);
        } else {
            NSLog(@"%% not connected (check identification and USB cable)\n",
                serial_or_name);
        }
        [YAPI FreeAPI];
    }
    return 0;
}
```

Each property `xxx` of the module can be read thanks to a method of type `get_xxxx`, and properties which are not read-only can be modified with the help of the `set_xxx` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `set xxx:` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `saveToFlash` method. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash` method. The short example below allows you to modify the logical name of a module.

```
#import <Foundation/Foundation.h>
#import "yocto_api.h"

static void usage(const char *exe)
{
    NSLog(@"usage: %s <serial> <newLogicalName>\n", exe);
    exit(1);
}

int main (int argc, const char * argv[])
{
    NSError *error;

    @autoreleasepool {
        // Setup the API to use local USB devices
        if([YAPI RegisterHub:@"usb" :&error] != YAPI_SUCCESS) {
            NSLog(@"RegisterHub error: %@", [error localizedDescription]);
            return 1;
        }

        if(argc < 2)
            usage(argv[0]);

        NSString *serial_or_name = [NSString stringWithUTF8String:argv[1]];
        // use serial or logical name
        YModule *module = [YModule FindModule:serial_or_name];

        if (module.isOnline) {
            if (argc >= 3) {
                NSString *newname = [NSString stringWithUTF8String:argv[2]];
                if (![YAPI CheckLogicalName:newname]) {
                    NSLog(@"Invalid name (%@)\n", newname);
                    usage(argv[0]);
                }
                module.logicalName = newname;
                [module saveToFlash];
            }
            NSLog(@"Current name: %@\n", module.logicalName);
        } else {
            NSLog(@"%@ not connected (check identification and USB cable)\n",
                serial_or_name);
        }
        [YAPI FreeAPI];
    }
    return 0;
}
```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `NULL`. Below a short example listing the connected modules.

```

#import <Foundation/Foundation.h>
#import "yocto_api.h"

int main (int argc, const char * argv[])
{
    NSError *error;

    @autoreleasepool {
        // Setup the API to use local USB devices
        if([YAPI RegisterHub:@"usb" :&error] != YAPI_SUCCESS) {
            NSLog(@"RegisterHub error: %@\n", [error localizedDescription]);
            return 1;
        }

        NSLog(@"Device list:\n");

        YModule *module = [YModule FirstModule];
        while (module != nil) {
            NSLog(@"%@ %@", module.serialNumber, module.productName);
            module = [module nextModule];
        }
        [YAPI FreeAPI];
    }
    return 0;
}

```

10.3. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

11. Using Yocto-PowerRelay with Visual Basic .NET

VisualBasic has long been the most favored entrance path to the Microsoft world. Therefore, we had to provide our library for this language, even if the new trend is shifting to C#. All the examples and the project models are tested with Microsoft VisualBasic 2010 Express, freely available on the Microsoft web site¹.

11.1. Installation

Download the Visual Basic Yoctopuce library from the Yoctopuce web site². There is no setup program, simply copy the content of the zip file into the directory of your choice. You mostly need the content of the `Sources` directory. The other directories contain the documentation and a few sample programs. All sample projects are Visual Basic 2010, projects, if you are using a previous version, you may have to recreate the projects structure from scratch.

11.2. Using the Yoctopuce API in a Visual Basic project

The Visual Basic.NET Yoctopuce library is composed of a DLL and of source files in Visual Basic. The DLL is not a .NET DLL, but a classic DLL, written in C, which manages the low level communications with the modules³. The source files in Visual Basic manage the high level part of the API. Therefore, you need both this DLL and the .vb files of the `sources` directory to create a project managing Yoctopuce modules.

Configuring a Visual Basic project

The following indications are provided for Visual Studio Express 2010, but the process is similar for other versions. Start by creating your project. Then, on the *Solution Explorer* panel, right click on your project, and select "Add" and then "Add an existing item".

A file selection window opens. Select the `yocto_api.vb` file and the files corresponding to the functions of the Yoctopuce modules that your project is going to manage. If in doubt, select all the files.

You then have the choice between simply adding these files to your project, or to add them as links (the **Add** button is in fact a scroll-down menu). In the first case, Visual Studio copies the selected files into your project. In the second case, Visual Studio simply keeps a link on the original files. We recommend you to use links, which makes updates of the library much easier.

¹ <http://www.microsoft.com/visualstudio/en-us/products/2010-editions/visual-basic-express>

² www.yoctopuce.com/EN/libraries.php

³ The sources of this DLL are available in the C++ API

Then add in the same manner the `yapi.dll` DLL, located in the `Sources/dll` directory⁴. Then, from the **Solution Explorer** window, right click on the DLL, select **Properties** and in the **Properties** panel, set the **Copy to output folder** to **always**. You are now ready to use your Yoctopuce modules from Visual Studio.

In order to keep them simple, all the examples provided in this documentation are console applications. Naturally, the libraries function in a strictly identical manner if you integrate them in an application with a graphical interface.

11.3. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a Visual Basic code snippet to use the Relay function.

```
[...]
Dim errmsg As String
Dim relay As YRelay

REM Get access to your device, connected locally on USB for instance
yRegisterHub("usb", errmsg)
relay = yFindRelay("RELAYHI1-123456.relay1")

REM Hot-plug is easy: just check that the device is online
If (relay.isOnline()) Then
    REM Use relay.set_state(), ...
End If
```

Let's look at these lines in more details.

yRegisterHub

The `yRegisterHub` function initializes the Yoctopuce API and indicates where the modules should be looked for. When used with the parameter `"usb"`, it will use the modules locally connected to the computer running the library. If the initialization does not succeed, this function returns a value different from `YAPI_SUCCESS` and `errmsg` contains the error message.

yFindRelay

The `yFindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number `RELAYHI1-123456` which you have named `"MyModule"`, and for which you have given the `relay1` function the name `"MyFunction"`. The following five calls are strictly equivalent, as long as `"MyFunction"` is defined only once.

```
relay = yFindRelay("RELAYHI1-123456.relay1")
relay = yFindRelay("RELAYHI1-123456.MyFunction")
relay = yFindRelay("MyModule.relay1")
relay = yFindRelay("MyModule.MyFunction")
relay = yFindRelay("MyFunction")
```

`yFindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `yFindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `yFindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `Y_STATE_A` for output A, and `Y_STATE_B` for output B.

⁴ Remember to change the filter of the selection window, otherwise the DLL will not show.

A real example

Launch Microsoft VisualBasic and open the corresponding sample project provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library.

In this example, you will recognize the functions explained above, but this time used with all side materials needed to make it work nicely as a small demo.

```
Module Module1

    Private Sub Usage()
        Dim execname = System.AppDomain.CurrentDomain.FriendlyName
        Console.WriteLine("Usage:")
        Console.WriteLine(execname + " <serial_number> [ A | B ]")
        Console.WriteLine(execname + " <logical_name> [ A | B ]")
        Console.WriteLine(execname + " any [ A | B ]")
        System.Threading.Thread.Sleep(2500)
    End Sub

    Sub Main()
        Dim argv() As String = System.Environment.GetCommandLineArgs()
        Dim errmsg As String = ""
        Dim target As String
        Dim relay As YRelay
        Dim state As Char

        If argv.Length < 3 Then Usage()

        target = argv(1)
        state = CChar(Mid(argv(2), 1, 1).ToUpper())

        REM Setup the API to use local USB devices
        If (yRegisterHub("usb", errmsg) <> YAPI_SUCCESS) Then
            Console.WriteLine("RegisterHub error: " + errmsg)
        End If

        If target = "any" Then
            relay = yFirstRelay()
            If relay Is Nothing Then
                Console.WriteLine("No module connected (check USB cable) ")
            End If
        Else
            relay = yFindRelay(target + ".relay1")
        End If

        If (relay.isOnline()) Then
            If state = "A" Then relay.set_state(Y_STATE_A) Else relay.set_state(Y_STATE_B)
        Else
            Console.WriteLine("Module not connected (check identification and USB cable)")
        End If
        yFreeAPI()
    End Sub

End Module
```

11.4. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```
Imports System.IO
Imports System.Environment

Module Module1

    Sub usage()
        Console.WriteLine("usage: demo <serial or logical name> [ON/OFF]")
    End Sub

End Module
```

```

End Sub

Sub Main()
    Dim argv() As String = System.Environment.GetCommandLineArgs()
    Dim errmsg As String = ""
    Dim m As ymodule

    If (yRegisterHub("usb", errmsg) <> YAPI_SUCCESS) Then
        Console.WriteLine("RegisterHub error:" + errmsg)
    End If

    If argv.Length < 2 Then usage()

    m = yFindModule(argv(1)) REM use serial or logical name
    If (m.isOnline()) Then
        If argv.Length > 2 Then
            If argv(2) = "ON" Then m.set_beacon(Y_BEACON_ON)
            If argv(2) = "OFF" Then m.set_beacon(Y_BEACON_OFF)
        End If
        Console.WriteLine("serial:      " + m.get_serialNumber())
        Console.WriteLine("logical name: " + m.get_logicalName())
        Console.WriteLine("luminosity:   " + Str(m.get_luminosity()))
        Console.WriteLine("beacon:      ")
        If (m.get_beacon() = Y_BEACON_ON) Then
            Console.WriteLine("ON")
        Else
            Console.WriteLine("OFF")
        End If
        Console.WriteLine("upTime:      " + Str(m.get_upTime() / 1000) + " sec")
        Console.WriteLine("USB current: " + Str(m.get_usbCurrent()) + " mA")
        Console.WriteLine("Logs:")
        Console.WriteLine(m.get_lastLogs())
    Else
        Console.WriteLine(argv(1) + " not connected (check identification and USB cable)")
    End If
    yFreeAPI()
End Sub

End Module

```

Each property `xxx` of the module can be read thanks to a method of type `get_xxxx()`, and properties which are not read-only can be modified with the help of the `set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

Module Module1

    Sub usage()

        Console.WriteLine("usage: demo <serial or logical name> <new logical name>")
    End Sub
End Sub

Sub Main()
    Dim argv() As String = System.Environment.GetCommandLineArgs()
    Dim errmsg As String = ""
    Dim newname As String
    Dim m As YModule

    If (argv.Length <> 3) Then usage()

    REM Setup the API to use local USB devices
    If yRegisterHub("usb", errmsg) <> YAPI_SUCCESS Then

```

```

        Console.WriteLine("RegisterHub error: " + errmsg)
    End
End If

m = yFindModule(argv(1)) REM use serial or logical name
If m.isOnline() Then
    newname = argv(2)
    If (Not yCheckLogicalName(newname)) Then
        Console.WriteLine("Invalid name (" + newname + ")")
    End
End If
m.set_logicalName(newname)
m.saveToFlash() REM do not forget this
Console.Write("Module: serial= " + m.get_serialNumber)
Console.Write(" / name= " + m.get_logicalName())
Else
    Console.Write("not connected (check identification and USB cable)")
End If
yFreeAPI()

End Sub

End Module

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `Nothing`. Below a short example listing the connected modules.

```

Module Module1

Sub Main()
    Dim M As ymodule
    Dim errmsg As String = ""

    REM Setup the API to use local USB devices
    If yRegisterHub("usb", errmsg) <> YAPI_SUCCESS Then
        Console.WriteLine("RegisterHub error: " + errmsg)
    End
End If

    Console.WriteLine("Device list")
    M = yFirstModule()
    While M IsNot Nothing
        Console.WriteLine(M.get_serialNumber() + " (" + M.get_productName() + ")")
        M = M.nextModule()
    End While
    yFreeAPI()
End Sub

End Module

```

11.5. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

12. Using Yocto-PowerRelay with C#

C# (pronounced C-Sharp) is an object-oriented programming language promoted by Microsoft, it is somewhat similar to Java. Like Visual-Basic and Delphi, it allows you to create Windows applications quite easily. All the examples and the project models are tested with Microsoft C# 2010 Express, freely available on the Microsoft web site¹.

12.1. Installation

Download the Visual C# Yoctopuce library from the Yoctopuce web site². There is no setup program, simply copy the content of the zip file into the directory of your choice. You mostly need the content of the `Sources` directory. The other directories contain the documentation and a few sample programs. All sample projects are Visual C# 2010, projects, if you are using a previous version, you may have to recreate the projects structure from scratch.

12.2. Using the Yoctopuce API in a Visual C# project

The Visual C#.NET Yoctopuce library is composed of a DLL and of source files in Visual C#. The DLL is not a .NET DLL, but a classic DLL, written in C, which manages the low level communications with the modules³. The source files in Visual C# manage the high level part of the API. Therefore, you need both this DLL and the .cs files of the `sources` directory to create a project managing Yoctopuce modules.

Configuring a Visual C# project

The following indications are provided for Visual Studio Express 2010, but the process is similar for other versions. Start by creating your project. Then, on the *Solution Explorer* panel, right click on your project, and select "Add" and then "Add an existing item".

A file selection window opens. Select the `yocto_api.cs` file and the files corresponding to the functions of the Yoctopuce modules that your project is going to manage. If in doubt, select all the files.

You then have the choice between simply adding these files to your project, or to add them as links (the **Add** button is in fact a scroll-down menu). In the first case, Visual Studio copies the selected files into your project. In the second case, Visual Studio simply keeps a link on the original files. We recommend you to use links, which makes updates of the library much easier.

¹ <http://www.microsoft.com/visualstudio/en-us/products/2010-editions/visual-csharp-express>

² www.yoctopuce.com/EN/libraries.php

³ The sources of this DLL are available in the C++ API

Then add in the same manner the `yapi.dll` DLL, located in the `Sources/dll` directory⁴. Then, from the **Solution Explorer** window, right click on the DLL, select **Properties** and in the **Properties** panel, set the **Copy to output folder** to **always**. You are now ready to use your Yoctopuce modules from Visual Studio.

In order to keep them simple, all the examples provided in this documentation are console applications. Naturally, the libraries function in a strictly identical manner if you integrate them in an application with a graphical interface.

12.3. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a C# code snippet to use the Relay function.

```
[...]
string errmsg = "";
YRelay relay;

// Get access to your device, connected locally on USB for instance
YAPI.RegisterHub("usb", errmsg);
relay = YRelay.FindRelay("RELAYHI1-123456.relay1");

// Hot-plug is easy: just check that the device is online
if (relay.isOnline())
{
    // Use relay.set_state(); ...
}
```

Let's look at these lines in more details.

YAPI.RegisterHub

The `YAPI.RegisterHub` function initializes the Yoctopuce API and indicates where the modules should be looked for. When used with the parameter `"usb"`, it will use the modules locally connected to the computer running the library. If the initialization does not succeed, this function returns a value different from `YAPI.SUCCESS` and `errmsg` contains the error message.

YRelay.FindRelay

The `YRelay.FindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number `RELAYHI1-123456` which you have named `"MyModule"`, and for which you have given the `relay1` function the name `"MyFunction"`. The following five calls are strictly equivalent, as long as `"MyFunction"` is defined only once.

```
relay = YRelay.FindRelay("RELAYHI1-123456.relay1");
relay = YRelay.FindRelay("RELAYHI1-123456.MyFunction");
relay = YRelay.FindRelay("MyModule.relay1");
relay = YRelay.FindRelay("MyModule.MyFunction");
relay = YRelay.FindRelay("MyFunction");
```

`YRelay.FindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `YRelay.FindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `YRelay.FindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `YRelay.STATE_A` for output A, and `YRelay.STATE_B` for output B.

⁴ Remember to change the filter of the selection window, otherwise the DLL will not show.

A real example

Launch Microsoft Visual C# and open the corresponding sample project provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library.

In this example, you will recognize the functions explained above, but this time used with all side materials needed to make it work nicely as a small demo.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace ConsoleApplication1
{
    class Program
    {
        static void usage()
        {
            string execname = System.AppDomain.CurrentDomain.FriendlyName;
            Console.WriteLine("Usage:");
            Console.WriteLine(execname + " <serial_number> [ A | B ]");
            Console.WriteLine(execname + " <logical_name> [ A | B ]");
            Console.WriteLine(execname + " any [ A | B ]");
            System.Threading.Thread.Sleep(2500);
            Environment.Exit(0);
        }

        static void Main(string[] args)
        {
            string errmsg = "";
            string target;
            YRelay relay;
            string state;

            if (args.Length < 2) usage();
            target = args[0].ToUpper();
            state = args[1].ToUpper();

            if (YAPI.RegisterHub("usb", ref errmsg) != YAPI.SUCCESS) {
                Console.WriteLine("RegisterHub error: " + errmsg);
                Environment.Exit(0);
            }

            if (target == "ANY") {
                relay = YRelay.FirstRelay();
                if (relay == null) {
                    Console.WriteLine("No module connected (check USB cable) ");
                    Environment.Exit(0);
                }
            } else relay = YRelay.FindRelay(target + ".relay1");

            if (relay.isOnline()) {
                if (state == "A") relay.set_state(YRelay.STATE_A);
                else relay.set_state(YRelay.STATE_B);
            } else {
                Console.WriteLine("Module not connected (check identification and USB cable)");
            }
            YAPI.FreeAPI();
        }
    }
}
```

12.4. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
```

```

namespace ConsoleApplication1
{
    class Program
    {
        static void usage()
        {
            string execname = System.AppDomain.CurrentDomain.FriendlyName;
            Console.WriteLine("Usage:");
            Console.WriteLine(execname + " <serial or logical name> [ON/OFF]");
            System.Threading.Thread.Sleep(2500);
            Environment.Exit(0);
        }

        static void Main(string[] args)
        {
            YModule m;
            string errormsg = "";

            if (YAPI.RegisterHub("usb", ref errormsg) != YAPI.SUCCESS) {
                Console.WriteLine("RegisterHub error: " + errormsg);
                Environment.Exit(0);
            }

            if (args.Length < 1) usage();

            m = YModule.FindModule(args[0]); // use serial or logical name

            if (m.isOnline()) {
                if (args.Length >= 2) {
                    if (args[1].ToUpper() == "ON") {
                        m.set_beacon(YModule.BEACON_ON);
                    }
                    if (args[1].ToUpper() == "OFF") {
                        m.set_beacon(YModule.BEACON_OFF);
                    }
                }

                Console.WriteLine("serial:      " + m.get_serialNumber());
                Console.WriteLine("logical name: " + m.get_logicalName());
                Console.WriteLine("luminosity:  " + m.get_luminosity().ToString());
                Console.WriteLine("beacon:      ");
                if (m.get_beacon() == YModule.BEACON_ON)
                    Console.WriteLine("ON");
                else
                    Console.WriteLine("OFF");
                Console.WriteLine("upTime:      " + (m.get_upTime() / 1000).ToString() + " sec");
                Console.WriteLine("USB current:  " + m.get_usbCurrent().ToString() + " mA");
                Console.WriteLine("Logs:\r\n" + m.get_lastLogs());
            } else {
                Console.WriteLine(args[0] + " not connected (check identification and USB cable)");
            }
            YAPI.FreeAPI();
        }
    }
}

```

Each property `xxx` of the module can be read thanks to a method of type `YModule.get_xxxx()`, and properties which are not read-only can be modified with the help of the `YModule.set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `YModule.set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `YModule.saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `YModule.revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace ConsoleApplication1
{
    class Program
    {
        static void usage()
        {
            string execname = System.AppDomain.CurrentDomain.FriendlyName;
            Console.WriteLine("Usage:");
            Console.WriteLine("usage: demo <serial or logical name> <new logical name>");
            System.Threading.Thread.Sleep(2500);
            Environment.Exit(0);
        }

        static void Main(string[] args)
        {
            YModule m;
            string errormsg = "";
            string newname;

            if (args.Length != 2) usage();

            if (YAPI.RegisterHub("usb", ref errormsg) != YAPI.SUCCESS) {
                Console.WriteLine("RegisterHub error: " + errormsg);
                Environment.Exit(0);
            }

            m = YModule.FindModule(args[0]); // use serial or logical name

            if (m.isOnline()) {
                newname = args[1];
                if (!YAPI.CheckLogicalName(newname)) {
                    Console.WriteLine("Invalid name (" + newname + ")");
                    Environment.Exit(0);
                }

                m.set_logicalName(newname);
                m.saveToFlash(); // do not forget this

                Console.Write("Module: serial= " + m.get_serialNumber());
                Console.WriteLine(" / name= " + m.get_logicalName());
            } else {
                Console.Write("not connected (check identification and USB cable)");
            }
            YAPI.FreeAPI();
        }
    }
}

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `YModule.saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `YModule.yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not null. Below a short example listing the connected modules.

```

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;

namespace ConsoleApplication1
{
    class Program
    {

```

```

{
    static void Main(string[] args)
    {
        YModule m;
        string errmsg = "";

        if (YAPI.RegisterHub("usb", ref errmsg) != YAPI.SUCCESS) {
            Console.WriteLine("RegisterHub error: " + errmsg);
            Environment.Exit(0);
        }

        Console.WriteLine("Device list");
        m = YModule.FirstModule();
        while (m != null) {
            Console.WriteLine(m.get_serialNumber() + " (" + m.get_productName() + ")");
            m = m.nextModule();
        }
        YAPI.FreeAPI();
    }
}

```

12.5. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

13. Using Yocto-PowerRelay with Delphi

Delphi is a descendent of Turbo-Pascal. Originally, Delphi was produced by Borland, Embarcadero now edits it. The strength of this language resides in its ease of use, as anyone with some notions of the Pascal language can develop a Windows application in next to no time. Its only disadvantage is to cost something¹.

Delphi libraries are provided not as VCL components, but directly as source files. These files are compatible with most Delphi versions.²

To keep them simple, all the examples provided in this documentation are console applications. Obviously, the libraries work in a strictly identical way with VCL applications.

You will soon notice that the Delphi API defines many functions which return objects. You do not need to deallocate these objects yourself, the API does it automatically at the end of the application.

13.1. Preparation

Go to the Yoctopuce web site and download the Yoctopuce Delphi libraries³. Uncompress everything in a directory of your choice, add the subdirectory *sources* in the list of directories of Delphi libraries.⁴

By default, the Yoctopuce Delphi library uses the *yapi.dll* DLL, all the applications you will create with Delphi must have access to this DLL. The simplest way to ensure this is to make sure *yapi.dll* is located in the same directory as the executable file of your application.

13.2. Control of the Relay function

Launch your Delphi environment, copy the *yapi.dll* DLL in a directory, create a new console application in the same directory, and copy-paste the piece of code below:

```
program helloworld;
{$APPTYPE CONSOLE}
uses
  SysUtils,
  yocto_api,
  yocto_relay;
```

¹ Actually, Borland provided free versions (for personal use) of Delphi 2006 and 2007. Look for them on the Internet, you may still be able to download them.

² Delphi libraries are regularly tested with Delphi 5 and Delphi XE2.

³ www.yoctopuce.com/EN/libraries.php

⁴ Use the **Tools / Environment options** menu.

```

Procedure Usage();
var
  exe : string;

begin
  exe:= ExtractFileName(paramstr(0));
  WriteLn(exe+' <serial_number> A|B');
  WriteLn(exe+' <logical_name> A|B');
  WriteLn(exe+' any A|B');
  WriteLn('');
  WriteLn('Example:');
  WriteLn(exe+' any B');
halt;
End;

procedure setRelayState(relay:TYRelay; state:boolean);
begin
  if relay.isOnline() then
    begin
      if state then relay.set_state(Y_STATE_B)
        else relay.set_state(Y_STATE_A);
    end
  else WriteLn('Module not connected (check identification and USB cable)');
end;

var

  relay      : TYRelay;
  errmsg     : string;

begin

  if (paramcount<2) then usage();

  // Setup the API to use local USB devices
  if yRegisterHub('usb', errmsg)<>YAPI_SUCCESS then
  begin
    Write('RegisterHub error: '+errmsg);
    exit;
  end;

  if paramstr(1)='any' then
  begin
    // try to first the first relay available
    relay := yFirstRelay();
    if relay=nil then
    begin
      writeln('No module connected (check USB cable)');
      halt;
    end
  end
  else // or use the one specified the command line
    relay:= YFindRelay(paramstr(1)+'.relay1');

  // make sure it connected
  if not relay.isOnline() then
  begin
    writeln('No module connected (check USB cable)');
    halt;
  end;

  // lets drive the relay
  if paramstr(2)='B' then setRelayState(relay,true)
    else setRelayState(relay,false);

  yFreeAPI();
end.

```

There are only a few really important lines in this sample example. We will look at them in details.

yocto_api and yocto_relay

These two units provide access to the functions allowing you to manage Yoctopuce modules. `yocto_api` must always be used, `yocto_relay` is necessary to manage modules containing a relay, such as Yocto-PowerRelay.

yRegisterHub

The `yRegisterHub` function initializes the Yoctopuce API and specifies where the modules should be looked for. When used with the parameter `'usb'`, it will use the modules locally connected to the computer running the library. If the initialization does not succeed, this function returns a value different from `YAPI_SUCCESS` and `errmsg` contains the error message.

yFindRelay

The `yFindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can also use logical names, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number `RELAYHI1-123456` which you have named `"MyModule"`, and for which you have given the `relay1` function the name `"MyFunction"`. The following five calls are strictly equivalent, as long as `"MyFunction"` is defined only once.

```
relay := yFindRelay("RELAYHI1-123456.relay1");
relay := yFindRelay("RELAYHI1-123456.MyFunction");
relay := yFindRelay("MyModule.relay1");
relay := yFindRelay("MyModule.MyFunction");
relay := yFindRelay("MyFunction");
```

`yFindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `yFindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `yFindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `Y_STATE_A` for output A, and `Y_STATE_B` for output B.

13.3. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```
program modulecontrol;
{$APPTYPE CONSOLE}
uses
  SysUtils,
  yocto_api;

const
  serial = 'RELAYHI1-123456'; // use serial number or logical name

procedure refresh(module:Tymodule) ;
begin
  if (module.isOnline()) then
    begin
      Writeln('');
      Writeln('Serial       : ' + module.get_serialNumber());
      Writeln('Logical name : ' + module.get_logicalName());
      Writeln('Luminosity  : ' + intToStr(module.get_luminosity()));
      Write('Beacon      :');
      if (module.get_beacon()=Y_BEACON_ON) then Writeln('on')
      else Writeln('off');
      Writeln('uptime      : ' + intToStr(module.get_upTime() div 1000)+'s');
      Writeln('USB current : ' + intToStr(module.get_usbCurrent())+'mA');
      Writeln('Logs        : ');
      Writeln(module.get_lastlogs());
      Writeln('');
      Writeln('r : refresh / b:beacon ON / space : beacon off');
    end
  else Writeln('Module not connected (check identification and USB cable)');
end;
```

```

procedure beacon(module:Tymodule;state:integer);
begin
    module.set_beacon(state);
    refresh(module);
end;

var
    module : TYModule;
    c      : char;
    errmsg : string;

begin
    // Setup the API to use local USB devices
    if yRegisterHub('usb', errmsg)<>YAPI_SUCCESS then
    begin
        Write('RegisterHub error: '+errmsg);
        exit;
    end;

    module := yFindModule(serial);
    refresh(module);

    repeat
        read(c);
        case c of
            'r': refresh(module);
            'b': beacon(module,Y_BEACON_ON);
            ' ': beacon(module,Y_BEACON_OFF);
        end;
    until c = 'x';
    yFreeAPI();
end.

```

Each property xxx of the module can be read thanks to a method of type `get_xxxx()`, and properties which are not read-only can be modified with the help of the `set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

program savesettings;
{$APPTYPE CONSOLE}
uses
    SysUtils,
    yocto_api;

const
    serial = 'RELAYHI1-123456'; // use serial number or logical name

var
    module : TYModule;
    errmsg : string;
    newname : string;

begin
    // Setup the API to use local USB devices
    if yRegisterHub('usb', errmsg)<>YAPI_SUCCESS then
    begin
        Write('RegisterHub error: '+errmsg);
        exit;
    end;

    module := yFindModule(serial);
    if (not(module.isOnline)) then
    begin
        writeln('Module not connected (check identification and USB cable)');
        exit;
    end;

```

```

end;

Writeln('Current logical name : '+module.get_logicalName());
Write('Enter new name : ');
Readln(newname);
if (not(yCheckLogicalName(newname))) then
begin
    Writeln('invalid logical name');
    exit;
end;
module.set_logicalName(newname);
module.saveToFlash();
yFreeAPI();
Writeln('logical name is now : '+module.get_logicalName());
end.

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `nil`. Below a short example listing the connected modules.

```

program inventory;
{$APPTYPE CONSOLE}
uses
    SysUtils,
    yocto_api;

var
    module : TYModule;
    errmsg : string;

begin
    // Setup the API to use local USB devices
    if yRegisterHub('usb', errmsg) <> YAPI_SUCCESS then
    begin
        Write('RegisterHub error: '+errmsg);
        exit;
    end;

    Writeln('Device list');

    module := yFirstModule();
    while module <> nil do
    begin
        Writeln( module.get_serialNumber()+' ('+module.get_productName()+')');
        module := module.nextModule();
    end;
    yFreeAPI();
end.

```

13.4. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then

hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

14. Using the Yocto-PowerRelay with Python

Python is an interpreted object oriented language developed by Guido van Rossum. Among its advantages is the fact that it is free, and the fact that it is available for most platforms, Windows as well as UNIX. It is an ideal language to write small scripts on a napkin. The Yoctopuce library is compatible with Python 2.6+ and 3+. It works under Windows, Mac OS X, and Linux, Intel as well as ARM. The library was tested with Python 2.6 and Python 3.2. Python interpreters are available on the Python web site¹.

14.1. Source files

The Yoctopuce library classes² for Python that you will use are provided as source files. Copy all the content of the *Sources* directory in the directory of your choice and add this directory to the *PYTHONPATH* environment variable. If you use an IDE to program in Python, refer to its documentation to configure it so that it automatically finds the API source files.

14.2. Dynamic library

A section of the low-level library is written in C, but you should not need to interact directly with it: it is provided as a DLL under Windows, as a *.so* files under UNIX, and as a *.dylib* file under Mac OS X. Everything was done to ensure the simplest possible interaction from Python: the distinct versions of the dynamic library corresponding to the distinct operating systems and architectures are stored in the *cdll* directory. The API automatically loads the correct file during its initialization. You should not have to worry about it.

If you ever need to recompile the dynamic library, its complete source code is located in the Yoctopuce C++ library.

In order to keep them simple, all the examples provided in this documentation are console applications. Naturally, the libraries function in a strictly identical manner if you integrate them in an application with a graphical interface.

14.3. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a Python code snippet to use the Relay function.

¹ <http://www.python.org/download/>

² www.yoctopuce.com/EN/libraries.php

```
[...]

errmsg=YRefParam()
#Get access to your device, connected locally on USB for instance
YAPI.RegisterHub("usb",errmsg)
relay = YRelay.FindRelay("RELAYHI1-123456.relay1")

# Hot-plug is easy: just check that the device is online
if relay.isOnline():
    #Use relay.set_state()
    ...

[...]
```

Let's look at these lines in more details.

YAPI.RegisterHub

The `yAPI.RegisterHub` function initializes the Yoctopuce API and indicates where the modules should be looked for. When used with the parameter "usb", it will use the modules locally connected to the computer running the library. If the initialization does not succeed, this function returns a value different from `YAPI.SUCCESS` and `errmsg` contains the error message.

YRelay.FindRelay

The `YRelay.FindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number *RELAYHI1-123456* which you have named "MyModule", and for which you have given the *relay1* function the name "MyFunction". The following five calls are strictly equivalent, as long as "MyFunction" is defined only once.

```
relay = YRelay.FindRelay("RELAYHI1-123456.relay1")
relay = YRelay.FindRelay("RELAYHI1-123456.MyFunction")
relay = YRelay.FindRelay("MyModule.relay1")
relay = YRelay.FindRelay("MyModule.MyFunction")
relay = YRelay.FindRelay("MyFunction")
```

`YRelay.FindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `YRelay.FindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `YRelay.FindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `YRelay.STATE_A` for output A, and `YRelay.STATE_B` for output B.

A real example

Launch Python and open the corresponding sample script provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library.

In this example, you will recognize the functions explained above, but this time used with all side materials needed to make it work nicely as a small demo.

```
#!/usr/bin/python
# -*- coding: utf-8 -*-
import os, sys

from yocto_api import *
from yocto_relay import *

def usage():
```

```

scriptname = os.path.basename(sys.argv[0])
print("Usage:")
print(scriptname + ' <serial_number> [ A | B ]')
print(scriptname + ' <logical_name> [ A | B ]')
print(scriptname + ' any [ A | B ]')
print('Example:')
print(scriptname + ' any B')
sys.exit()

def die(msg):
    sys.exit(msg + ' (check USB cable)')

if len(sys.argv) < 2:
    usage()

target = sys.argv[1].upper()
state = sys.argv[2].upper()

# Setup the API to use local USB devices
errmsg = YRefParam()
if YAPI.RegisterHub("usb", errmsg) != YAPI.SUCCESS:
    sys.exit("init error" + errmsg.value)

if target == 'ANY':
    # retrieve any Relay
    relay = YRelay.FirstRelay()
    if relay is None:
        die('no device connected')
else:
    relay = YRelay.FindRelay(target + ".relay1")

if not (relay.isOnline()):
    die('device not connected')

if state == 'A':
    relay.set_state(YRelay.STATE_A)
else:
    relay.set_state(YRelay.STATE_B)
YAPI.FreeAPI()

```

14.4. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```

#!/usr/bin/python
# -*- coding: utf-8 -*-
import os, sys

from yocto_api import *

def usage():
    sys.exit("usage: demo <serial or logical name> [ON/OFF]")

errmsg = YRefParam()
if YAPI.RegisterHub("usb", errmsg) != YAPI.SUCCESS:
    sys.exit("RegisterHub error: " + str(errmsg))

if len(sys.argv) < 2:
    usage()

m = YModule.FindModule(sys.argv[1]) # use serial or logical name

if m.isOnline():
    if len(sys.argv) > 2:
        if sys.argv[2].upper() == "ON":
            m.set_beacon(YModule.BEACON_ON)
        if sys.argv[2].upper() == "OFF":
            m.set_beacon(YModule.BEACON_OFF)

```

```

print("serial:      " + m.get_serialNumber())
print("logical name: " + m.get_logicalName())
print("luminosity:   " + str(m.get_luminosity()))
if m.get_beacon() == YModule.BEACON_ON:
    print("beacon:      ON")
else:
    print("beacon:      OFF")
print("upTime:       " + str(m.get_upTime() / 1000) + " sec")
print("USB current:  " + str(m.get_usbCurrent()) + " mA")
print("logs:\n" + m.get_lastLogs())
else:
    print(sys.argv[1] + " not connected (check identification and USB cable)")
YAPI.FreeAPI()

```

Each property `xxx` of the module can be read thanks to a method of type `YModule.get_xxxx()`, and properties which are not read-only can be modified with the help of the `YModule.set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `YModule.set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `YModule.saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `YModule.revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

#!/usr/bin/python
# -*- coding: utf-8 -*-
import os, sys

from yocto_api import *

def usage():
    sys.exit("usage: demo <serial or logical name> <new logical name>")

if len(sys.argv) != 3:
    usage()

errmsg = YRefParam()
if YAPI.RegisterHub("usb", errmsg) != YAPI.SUCCESS:
    sys.exit("RegisterHub error: " + str(errmsg))

m = YModule.FindModule(sys.argv[1]) # use serial or logical name
if m.isOnline():
    newname = sys.argv[2]
    if not YAPI.CheckLogicalName(newname):
        sys.exit("Invalid name (" + newname + ")")
    m.set_logicalName(newname)
    m.saveToFlash() # do not forget this
    print("Module: serial= " + m.get_serialNumber() + " / name= " + m.get_logicalName())
else:
    sys.exit("not connected (check identification and USB cable)")
YAPI.FreeAPI()

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `YModule.saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `YModule.yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `null`. Below a short example listing the connected modules.

```
#!/usr/bin/python
# -*- coding: utf-8 -*-
import os, sys

from yocto_api import *

errmsg = YRefParam()

# Setup the API to use local USB devices
if YAPI.RegisterHub("usb", errmsg) != YAPI.SUCCESS:
    sys.exit("init error" + str(errmsg))

print('Device list')

module = YModule.FirstModule()
while module is not None:
    print(module.get_serialNumber() + ' (' + module.get_productName() + ')')
    module = module.nextModule()
YAPI.FreeAPI()
```

14.5. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software. The only way to prevent this is to implement one of the two error handling techniques described below.

The method recommended by most programming languages for unpredictable error handling is the use of exceptions. By default, it is the behavior of the Yoctopuce library. If an error happens while you try to access a module, the library throws an exception. In this case, there are three possibilities:

- If your code catches the exception and handles it, everything goes well.
- If your program is running in debug mode, you can relatively easily determine where the problem happened and view the explanatory message linked to the exception.
- Otherwise... the exception makes your program crash, bang!

As this latest situation is not the most desirable, the Yoctopuce library offers another possibility for error handling, allowing you to create a robust program without needing to catch exceptions at every line of code. You simply need to call the `YAPI.DisableExceptions()` function to commute the library to a mode where exceptions for all the functions are systematically replaced by specific return values, which can be tested by the caller when necessary. For each function, the name of each return value in case of error is systematically documented in the library reference. The name always follows the same logic: a `get_state()` method returns a `Y_STATE_INVALID` value, a `get_currentValue` method returns a `Y_CURRENTVALUE_INVALID` value, and so on. In any case, the returned value is of the expected type and is not a null pointer which would risk crashing your program. At worst, if you display the value without testing it, it will be outside the expected bounds for the returned value. In the case of functions which do not normally return information, the return value is `YAPI_SUCCESS` if everything went well, and a different error code in case of failure.

When you work without exceptions, you can obtain an error code and an error message explaining the source of the error. You can request them from the object which returned the error, calling the `errType()` and `errorMessage()` methods. Their returned values contain the same information as in the exceptions when they are active.

15. Using the Yocto-PowerRelay with Java

Java is an object oriented language created by Sun Microsystem. Beside being free, its main strength is its portability. Unfortunately, this portability has an excruciating price. In Java, hardware abstraction is so high that it is almost impossible to work directly with the hardware. Therefore, the Yoctopuce API does not support native mode in regular Java. The Java API needs a Virtual Hub to communicate with Yoctopuce devices.

15.1. Getting ready

Go to the Yoctopuce web site and download the following items:

- The Java programming library¹
- The VirtualHub software² for Windows, Mac OS X or Linux, depending on your OS

The library is available as source files as well as a *jar* file. Decompress the library files in a folder of your choice, connect your modules, run the VirtualHub software, and you are ready to start your first tests. You do not need to install any driver.

In order to keep them simple, all the examples provided in this documentation are console applications. Naturally, the libraries function in a strictly identical manner if you integrate them in an application with a graphical interface.

15.2. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a Java code snippet to use the Relay function.

```
[...]

// Get access to your device, connected locally on USB for instance
YAPI.RegisterHub("127.0.0.1");
relay = YRelay.FindRelay("RELAYHI1-123456.relay1");

// Hot-plug is easy: just check that the device is online
if (relay.isOnline())
{
    // Use relay.set_state()
    [...]
}
```

¹ www.yoctopuce.com/EN/libraries.php

² www.yoctopuce.com/EN/virtualhub.php

```
}
[...]
```

Let us look at these lines in more details.

YAPI.RegisterHub

The `yAPI.RegisterHub` function initializes the Yoctopuce API and indicates where the modules should be looked for. The parameter is the address of the Virtual Hub able to see the devices. If the initialization does not succeed, an exception is thrown.

YRelay.FindRelay

The `YRelay.FindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number *RELAYHI1-123456* which you have named "MyModule", and for which you have given the *relay1* function the name "MyFunction". The following five calls are strictly equivalent, as long as "MyFunction" is defined only once.

```
relay = YRelay.FindRelay("RELAYHI1-123456.relay1")
relay = YRelay.FindRelay("RELAYHI1-123456.MyFunction")
relay = YRelay.FindRelay("MyModule.relay1")
relay = YRelay.FindRelay("MyModule.MyFunction")
relay = YRelay.FindRelay("MyFunction")
```

`YRelay.FindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `YRelay.FindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the object returned by `YRelay.FindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `YRelay.STATE_A` for output A, and `YRelay.STATE_B` for output B.

A real example

Launch your Java environment and open the corresponding sample project provided in the directory **Examples/Doc-GettingStarted-Yocto-PowerRelay** of the Yoctopuce library.

In this example, you will recognize the functions explained above, but this time used with all the side materials needed to make it work nicely as a small demo.

```
import com.yoctopuce.YoctoAPI.*;

public class Demo {

    public static void main(String[] args) {
        try {
            // setup the API to use local VirtualHub
            YAPI.RegisterHub("127.0.0.1");
        } catch (YAPI_Exception ex) {
            System.out.println("Cannot contact VirtualHub on 127.0.0.1 (" +
ex.getLocalizedMessage() + ")");
            System.out.println("Ensure that the VirtualHub application is running");
            System.exit(1);
        }

        YRelay relay;
        if (args.length > 0) {
            relay = YRelay.FindRelay(args[0]);
        } else {
            relay = YRelay.FirstRelay();
            if (relay == null) {
```

```

        System.out.println("No module connected (check USB cable)");
        System.exit(1);
    }

    try {

        System.out.println("Switch relay to B");
        relay.set_state(YRelay.STATE_B);
        YAPI.Sleep(1000);
        System.out.println("Switch relay to A");
        relay.set_state(YRelay.STATE_A);
    } catch (YAPI_Exception ex) {
        System.out.println("Module "+relay.describe()+" not connected (check
identification and USB cable)");
    }
    YAPI.FreeAPI();
}
}

```

15.3. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```

import com.yoctopuce.YoctoAPI.*;
import java.util.logging.Level;
import java.util.logging.Logger;

public class Demo {

    public static void main(String[] args)
    {
        try {
            // setup the API to use local VirtualHub
            YAPI.RegisterHub("127.0.0.1");
        } catch (YAPI_Exception ex) {
            System.out.println("Cannot contact VirtualHub on 127.0.0.1 (" +
ex.getLocalizedMessage() + ")");
            System.out.println("Ensure that the VirtualHub application is running");
            System.exit(1);
        }
        System.out.println("usage: demo [serial or logical name] [ON/OFF]");

        YModule module;
        if (args.length == 0) {
            module = YModule.FirstModule();
            if (module == null) {
                System.out.println("No module connected (check USB cable)");
                System.exit(1);
            }
        } else {
            module = YModule.FindModule(args[0]); // use serial or logical name
        }

        try {
            if (args.length > 1) {
                if (args[1].equalsIgnoreCase("ON")) {
                    module.setBeacon(YModule.BEACON_ON);
                } else {
                    module.setBeacon(YModule.BEACON_OFF);
                }
            }
            System.out.println("serial:      " + module.get_serialNumber());
            System.out.println("logical name: " + module.get_logicalName());
            System.out.println("luminosity:  " + module.get_luminosity());
            if (module.get_beacon() == YModule.BEACON_ON) {
                System.out.println("beacon:      ON");
            } else {
                System.out.println("beacon:      OFF");
            }
        }
        System.out.println("upTime:      " + module.get_upTime() / 1000 + " sec");
    }
}

```

```

        System.out.println("USB current: " + module.get_usbCurrent() + " mA");
        System.out.println("logs:\n" + module.get_lastLogs());
    } catch (YAPI_Exception ex) {
        System.out.println(args[1] + " not connected (check identification and USB
cable)");
    }
    YAPI.FreeAPI();
}
}

```

Each property `xxx` of the module can be read thanks to a method of type `YModule.get_xxxx()`, and properties which are not read-only can be modified with the help of the `YModule.set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `YModule.set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `YModule.saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `YModule.revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

import com.yoctopuce.YoctoAPI.*;

public class Demo {

    public static void main(String[] args)
    {
        try {
            // setup the API to use local VirtualHub
            YAPI.RegisterHub("127.0.0.1");
        } catch (YAPI_Exception ex) {
            System.out.println("Cannot contact VirtualHub on 127.0.0.1 (" +
ex.getLocalizedMessage() + ")");
            System.out.println("Ensure that the VirtualHub application is running");
            System.exit(1);
        }

        if (args.length != 2) {
            System.out.println("usage: demo <serial or logical name> <new logical name>");
            System.exit(1);
        }

        YModule m;
        String newname;

        m = YModule.FindModule(args[0]); // use serial or logical name

        try {
            newname = args[1];
            if (!YAPI.CheckLogicalName(newname))
            {
                System.out.println("Invalid name (" + newname + ")");
                System.exit(1);
            }

            m.set_logicalName(newname);
            m.saveToFlash(); // do not forget this

            System.out.println("Module: serial= " + m.get_serialNumber());
            System.out.println(" / name= " + m.get_logicalName());
        } catch (YAPI_Exception ex) {
            System.out.println("Module " + args[0] + "not connected (check identification
and USB cable)");
            System.out.println(ex.getMessage());
            System.exit(1);
        }

        YAPI.FreeAPI();
    }
}

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `YModule.saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `YModule.yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `null`. Below a short example listing the connected modules.

```
import com.yoctopuce.YoctoAPI.*;

public class Demo {

    public static void main(String[] args)
    {
        try {
            // setup the API to use local VirtualHub
            YAPI.RegisterHub("127.0.0.1");
        } catch (YAPI_Exception ex) {
            System.out.println("Cannot contact VirtualHub on 127.0.0.1 (" +
ex.getLocalizedMessage() + ")");
            System.out.println("Ensure that the VirtualHub application is running");
            System.exit(1);
        }

        System.out.println("Device list");
        YModule module = YModule.FirstModule();
        while (module != null) {
            try {
                System.out.println(module.get_serialNumber() + " (" +
module.get_productName() + ")");
            } catch (YAPI_Exception ex) {
                break;
            }
            module = module.nextModule();
        }
        YAPI.FreeAPI();
    }
}
```

15.4. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software.

In the Java API, error handling is implemented with exceptions. Therefore you must catch and handle correctly all exceptions that might be thrown by the API if you do not want your software to crash as soon as you unplug a device.

16. Using the Yocto-PowerRelay with Android

To tell the truth, Android is not a programming language, it is an operating system developed by Google for mobile appliances such as smart phones and tablets. But it so happens that under Android everything is programmed with the same programming language: Java. Nevertheless, the programming paradigms and the possibilities to access the hardware are slightly different from classical Java, and this justifies a separate chapter on Android programming.

16.1. Native access and VirtualHub

In the opposite to the classical Java API, the Java for Android API can access USB modules natively. However, as there is no VirtualHub running under Android, it is not possible to remotely control Yoctopuce modules connected to a machine under Android. Naturally, the Java for Android API remains perfectly able to connect itself to a VirtualHub running on another OS.

16.2. Getting ready

Go to the Yoctopuce web site and download the Java for Android programming library¹. The library is available as source files, and also as a jar file. Connect your modules, decompress the library files in the directory of your choice, and configure your Android programming environment so that it can find them.

To keep them simple, all the examples provided in this documentation are snippets of Android applications. You must integrate them in your own Android applications to make them work. However, you can find complete applications in the examples provided with the Java for Android library.

16.3. Compatibility

In an ideal world, you would only need to have a smart phone running under Android to be able to make Yoctopuce modules work. Unfortunately, it is not quite so in the real world. A machine running under Android must fulfil a few requirements to be able to manage Yoctopuce USB modules natively.

¹ www.yoctopuce.com/EN/libraries.php

Android 4.x

Android 4.0 (api 14) and following are officially supported. Theoretically, support of USB *host* functions since Android 3.1. But be aware that the Yoctopuce Java for Android API is regularly tested only from Android 4 onwards.

USB *host* support

Naturally, not only must your machine have a USB port, this port must also be able to run in *host* mode. In *host* mode, the machine literally takes control of the devices which are connected to it. The USB ports of a desktop computer, for example, work in *host* mode. The opposite of the *host* mode is the *device* mode. USB keys, for instance, work in *device* mode: they must be controlled by a *host*. Some USB ports are able to work in both modes, they are *OTG (On The Go)* ports. It so happens that many mobile devices can only work in *device* mode: they are designed to be connected to a charger or a desktop computer, and nothing else. It is therefore highly recommended to pay careful attention to the technical specifications of a product working under Android before hoping to make Yoctopuce modules work with it.

Unfortunately, having a correct version of Android and USB ports working in *host* mode is not enough to guaranty that Yoctopuce modules will work well under Android. Indeed, some manufacturers configure their Android image so that devices other than keyboard and mass storage are ignored, and this configuration is hard to detect. As things currently stand, the best way to know if a given Android machine works with Yoctopuce modules consists in trying.

Supported hardware

The library is tested and validated on the following machines:

- Samsung Galaxy S3
- Samsung Galaxy Note 2
- Google Nexus 5
- Google Nexus 7
- Acer Iconia Tab A200
- Asus Tranformer Pad TF300T
- Kurio 7

If your Android machine is not able to control Yoctopuce modules natively, you still have the possibility to remotely control modules driven by a VirtualHub on another OS, or a YoctoHub ².

16.4. Activating the USB port under Android

By default, Android does not allow an application to access the devices connected to the USB port. To enable your application to interact with a Yoctopuce module directly connected on your tablet on a USB port, a few additional steps are required. If you intend to interact only with modules connected on another machine through the network, you can ignore this section.

In your `AndroidManifest.xml`, you must declare using the "USB Host" functionality by adding the `<uses-feature android:name="android.hardware.usb.host" />` tag in the `manifest` section.

```
<manifest ...>
...
<uses-feature android:name="android.hardware.usb.host" />;
...
</manifest>
```

When first accessing a Yoctopuce module, Android opens a window to inform the user that the application is going to access the connected module. The user can deny or authorize access to the device. If the user authorizes the access, the application can access the connected device as long as

² Yoctohubs are a plug and play way to add network connectivity to your Yoctopuce devices. more info on <http://www.yoctopuce.com/EN/products/category/extensions-and-networking>

it stays connected. To enable the Yoctopuce library to correctly manage these authorizations, you must provide a pointer on the application context by calling the `EnableUSBHost` method of the `YAPI` class before the first USB access. This function takes as arguments an object of the `android.content.Context` class (or of a subclass). As the `Activity` class is a subclass of `Context`, it is simpler to call `YAPI.EnableUSBHost(this)`; in the method `onCreate` of your application. If the object passed as parameter is not of the correct type, a `YAPI_Exception` exception is generated.

```
...
@Override
public void onCreate(Bundle savedInstanceState) {
    super.onCreate(savedInstanceState);
    try {
        // Pass the application Context to the Yoctopuce Library
        YAPI.EnableUSBHost(this);
    } catch (YAPI_Exception e) {
        Log.e("Yocto", e.getLocalizedMessage());
    }
}
...
```

Autorun

It is possible to register your application as a default application for a USB module. In this case, as soon as a module is connected to the system, the application is automatically launched. You must add `<action android:name="android.hardware.usb.action.USB_DEVICE_ATTACHED"/>` in the section `<intent-filter>` of the main activity. The section `<activity>` must have a pointer to an XML file containing the list of USB modules which can run the application.

```
<manifest xmlns:android="http://schemas.android.com/apk/res/android"
...
<uses-feature android:name="android.hardware.usb.host" />
...
<application ... >
    <activity
        android:name=".MainActivity" >
        <intent-filter>
            <action android:name="android.intent.action.MAIN" />
            <action android:name="android.hardware.usb.action.USB_DEVICE_ATTACHED" />
            <category android:name="android.intent.category.LAUNCHER" />
        </intent-filter>

        <meta-data
            android:name="android.hardware.usb.action.USB_DEVICE_ATTACHED"
            android:resource="@xml/device_filter" />
        </activity>
    </application>
</manifest>
```

The XML file containing the list of modules allowed to run the application must be saved in the `res/xml` directory. This file contains a list of USB *vendorId* and *deviceId* in decimal. The following example runs the application as soon as a Yocto-Relay or a YoctoPowerRelay is connected. You can find the *vendorId* and the *deviceId* of Yoctopuce modules in the characteristics section of the documentation.

```
<?xml version="1.0" encoding="utf-8"?>

<resources>
    <usb-device vendor-id="9440" product-id="12" />
    <usb-device vendor-id="9440" product-id="13" />
</resources>
```

16.5. Control of the Relay function

A few lines of code are enough to use a Yocto-PowerRelay. Here is the skeleton of a Java code snippet to use the Relay function.

```
[...]

// Retrieving the object representing the module (connected here locally by USB)
YAPI.EnableUSBHost(this);
YAPI.RegisterHub("usb");
relay = YRelay.FindRelay("RELAYHI1-123456.relay1");

// Hot-plug is easy: just check that the device is online
if (relay.isOnline())
{ //Use relay.set_state()
  ...
}

[...]
```

Let us look at these lines in more details.

YAPI.EnableUSBHost

The `YAPI.EnableUSBHost` function initializes the API with the Context of the current application. This function takes as argument an object of the `android.content.Context` class (or of a subclass). If you intend to connect your application only to other machines through the network, this function is facultative.

YAPI.RegisterHub

The `yAPI.RegisterHub` function initializes the Yoctopuce API and indicates where the modules should be looked for. The parameter is the address of the virtual hub able to see the devices. If the string "usb" is passed as parameter, the API works with modules locally connected to the machine. If the initialization does not succeed, an exception is thrown.

YRelay.FindRelay

The `YRelay.FindRelay` function allows you to find a relay from the serial number of the module on which it resides and from its function name. You can use logical names as well, as long as you have initialized them. Let us imagine a Yocto-PowerRelay module with serial number *RELAYHI1-123456* which you have named "MyModule", and for which you have given the *relay1* function the name "MyFunction". The following five calls are strictly equivalent, as long as "MyFunction" is defined only once.

```
relay = YRelay.FindRelay("RELAYHI1-123456.relay1")
relay = YRelay.FindRelay("RELAYHI1-123456.MyFunction")
relay = YRelay.FindRelay("MyModule.relay1")
relay = YRelay.FindRelay("MyModule.MyFunction")
relay = YRelay.FindRelay("MyFunction")
```

`YRelay.FindRelay` returns an object which you can then use at will to control the relay.

isOnline

The `isOnline()` method of the object returned by `YRelay.FindRelay` allows you to know if the corresponding module is present and in working order.

set_state

The `set_state()` method of the objet returned by `YRelay.FindRelay` switches the relay position to one of its two outputs. The two possible parameter values are `YRelay.STATE_A` for output A, and `YRelay.STATE_B` for output B.

A real example

Launch your Java environment and open the corresponding sample project provided in the directory **Examples//Doc-Examples** of the Yoctopuce library.

In this example, you can recognize the functions explained above, but this time used with all the side materials needed to make it work nicely as a small demo.

```
package com.yoctopuce.doc_examples;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.Spinner;

import com.yoctopuce.YoctoAPI.YAPI;
import com.yoctopuce.YoctoAPI.YAPI_Exception;
import com.yoctopuce.YoctoAPI.YRelay;

public class GettingStarted_Yocto_PowerRelay extends Activity implements
OnItemClickListener
{
    private YRelay relay = null;
    private ArrayAdapter<String> aa;

    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.gettingstarted_yocto_powerrelay);
        Spinner my_spin = (Spinner) findViewById(R.id.spinner1);
        my_spin.setOnItemClickListener(this);
        aa = new ArrayAdapter<String>(this, android.R.layout.simple_spinner_item);
        aa.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
        my_spin.setAdapter(aa);
    }

    @Override
    protected void onStart()
    {
        super.onStart();

        try {
            aa.clear();
            YAPI.EnableUSBHost(this);
            YAPI.RegisterHub("usb");
            YRelay r = YRelay.FirstRelay();
            while (r != null) {
                String hwid = r.get_hardwareId();
                aa.add(hwid);
                r = r.nextRelay();
            }
        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
        // refresh Spinner with detected relay
        aa.notifyDataSetChanged();
    }

    @Override
    protected void onStop()
    {
        super.onStop();
        YAPI.FreeAPI();
    }

    @Override
    public void onItemClick(AdapterView<?> parent, View view, int pos, long id)
    {
        String hwid = parent.getItemAtPosition(pos).toString();
        relay = YRelay.FindRelay(hwid);
    }
}
```

```

@Override
public void onNothingSelected(AdapterView<?> arg0)
{
}

/** Called when the user touches the button State A */
public void setStateA(View view)
{
    // Do something in response to button click
    if (relay != null)
        try {
            relay.setState(YRelay.STATE_A);
        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
}

/** Called when the user touches the button State B */
public void setStateB(View view)
{
    // Do something in response to button click
    if (relay != null)
        try {
            relay.setState(YRelay.STATE_B);
        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
}
}

```

16.6. Control of the module part

Each module can be controlled in a similar manner, you can find below a simple sample program displaying the main parameters of the module and enabling you to activate the localization beacon.

```

package com.yoctopuce.doc_examples;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.Spinner;
import android.widget.Switch;
import android.widget.TextView;

import com.yoctopuce.YoctoAPI.YAPI;
import com.yoctopuce.YoctoAPI.YAPI_Exception;
import com.yoctopuce.YoctoAPI.YModule;

public class ModuleControl extends Activity implements OnItemClickListener
{
    private ArrayAdapter<String> aa;
    private YModule module = null;

    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.modulecontrol);
        Spinner my_spin = (Spinner) findViewById(R.id.spinner1);
        my_spin.setOnItemClickListener(this);
        aa = new ArrayAdapter<String>(this, android.R.layout.simple_spinner_item);
        aa.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
        my_spin.setAdapter(aa);
    }

    @Override
    protected void onStart()
    {

```

```

super.onStart();

try {
    aa.clear();
    YAPI.EnableUSBHost(this);
    YAPI.RegisterHub("usb");
    YModule r = YModule.FirstModule();
    while (r != null) {
        String hwid = r.get_hardwareId();
        aa.add(hwid);
        r = r.nextModule();
    }
} catch (YAPI_Exception e) {
    e.printStackTrace();
}
// refresh Spinner with detected relay
aa.notifyDataSetChanged();
}

@Override
protected void onStop()
{
    super.onStop();
    YAPI.FreeAPI();
}

private void DisplayModuleInfo()
{
    TextView field;
    if (module == null)
        return;
    try {
        field = (TextView) findViewById(R.id.serialfield);
        field.setText(module.getSerialNumber());
        field = (TextView) findViewById(R.id.logicalnamefield);
        field.setText(module.getLogicalName());
        field = (TextView) findViewById(R.id.luminosityfield);
        field.setText(String.format("%d%%", module.getLuminosity()));
        field = (TextView) findViewById(R.id.uptimefield);
        field.setText(module.getUpTime() / 1000 + " sec");
        field = (TextView) findViewById(R.id.usbcurrentfield);
        field.setText(module.getUsbCurrent() + " mA");
        Switch sw = (Switch) findViewById(R.id.beaconswitch);
        sw.setChecked(module.getBeacon() == YModule.BEACON_ON);
        field = (TextView) findViewById(R.id.logs);
        field.setText(module.get_lastLogs());

    } catch (YAPI_Exception e) {
        e.printStackTrace();
    }
}

@Override
public void onItemClick(AdapterView<?> parent, View view, int pos, long id)
{
    String hwid = parent.getItemAtPosition(pos).toString();
    module = YModule.FindModule(hwid);
    DisplayModuleInfo();
}

@Override
public void onNothingSelected(AdapterView<?> arg0)
{
}

public void refreshInfo(View view)
{
    DisplayModuleInfo();
}

public void toggleBeacon(View view)
{
    if (module == null)
        return;
    boolean on = ((Switch) view).isChecked();

    try {
        if (on) {

```

```

        module.setBeacon(YModule.BEACON_ON);
    } else {
        module.setBeacon(YModule.BEACON_OFF);
    }
} catch (YAPI_Exception e) {
    e.printStackTrace();
}
}
}

```

Each property `xxx` of the module can be read thanks to a method of type `YModule.get_xxx()`, and properties which are not read-only can be modified with the help of the `YModule.set_xxx()` method. For more details regarding the used functions, refer to the API chapters.

Changing the module settings

When you want to modify the settings of a module, you only need to call the corresponding `YModule.set_xxx()` function. However, this modification is performed only in the random access memory (RAM) of the module: if the module is restarted, the modifications are lost. To memorize them persistently, it is necessary to ask the module to save its current configuration in its permanent memory. To do so, use the `YModule.saveToFlash()` method. Inversely, it is possible to force the module to forget its current settings by using the `YModule.revertFromFlash()` method. The short example below allows you to modify the logical name of a module.

```

package com.yoctopuce.doc_examples;

import android.app.Activity;
import android.os.Bundle;
import android.view.View;
import android.widget.AdapterView;
import android.widget.AdapterView.OnItemClickListener;
import android.widget.ArrayAdapter;
import android.widget.EditText;
import android.widget.Spinner;
import android.widget.TextView;
import android.widget.Toast;

import com.yoctopuce.YoctoAPI.YAPI;
import com.yoctopuce.YoctoAPI.YAPI_Exception;
import com.yoctopuce.YoctoAPI.YModule;

public class SaveSettings extends Activity implements OnItemClickListener
{
    private ArrayAdapter<String> aa;
    private YModule module = null;

    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.savesettings);
        Spinner my_spin = (Spinner) findViewById(R.id.spinner1);
        my_spin.setOnItemClickListener(this);
        aa = new ArrayAdapter<String>(this, android.R.layout.simple_spinner_item);
        aa.setDropDownViewResource(android.R.layout.simple_spinner_dropdown_item);
        my_spin.setAdapter(aa);
    }

    @Override
    protected void onStart()
    {
        super.onStart();

        try {
            aa.clear();
            YAPI.EnableUSBHost(this);
            YAPI.RegisterHub("usb");
            YModule r = YModule.FirstModule();
            while (r != null) {
                String hwid = r.get_hardwareId();
                aa.add(hwid);
                r = r.nextModule();
            }
        }
    }
}

```

```

        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
        // refresh Spinner with detected relay
        aa.notifyDataSetChanged();
    }

    @Override
    protected void onStop()
    {
        super.onStop();
        YAPI.FreeAPI();
    }

    private void DisplayModuleInfo()
    {
        TextView field;
        if (module == null)
            return;
        try {
            YAPI.UpdateDeviceList(); // fixme
            field = (TextView) findViewById(R.id.logicalnamefield);
            field.setText(module.getLogicalName());
        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
    }

    @Override
    public void onItemClick(AdapterView<?> parent, View view, int pos, long id)
    {
        String hwid = parent.getItemAtPosition(pos).toString();
        module = YModule.FindModule(hwid);
        DisplayModuleInfo();
    }

    @Override
    public void onNothingSelected(AdapterView<?> arg0)
    {
    }

    public void saveName(View view)
    {
        if (module == null)
            return;

        EditText edit = (EditText) findViewById(R.id.newname);
        String newname = edit.getText().toString();
        try {
            if (!YAPI.CheckLogicalName(newname)) {
                Toast.makeText(getApplicationContext(), "Invalid name (" + newname + ")",
                    Toast.LENGTH_LONG).show();
                return;
            }
            module.set_logicalName(newname);
            module.saveToFlash(); // do not forget this
            edit.setText("");
        } catch (YAPI_Exception ex) {
            ex.printStackTrace();
        }
        DisplayModuleInfo();
    }
}

```

Warning: the number of write cycles of the nonvolatile memory of the module is limited. When this limit is reached, nothing guaranties that the saving process is performed correctly. This limit, linked to the technology employed by the module micro-processor, is located at about 100000 cycles. In short, you can use the `YModule.saveToFlash()` function only 100000 times in the life of the module. Make sure you do not call this function within a loop.

Listing the modules

Obtaining the list of the connected modules is performed with the `YModule.yFirstModule()` function which returns the first module found. Then, you only need to call the `nextModule()` function of this object to find the following modules, and this as long as the returned value is not `null`. Below a short example listing the connected modules.

```
package com.yoctopuce.doc_examples;

import android.app.Activity;
import android.os.Bundle;
import android.util.TypedValue;
import android.view.View;
import android.widget.LinearLayout;
import android.widget.TextView;

import com.yoctopuce.YoctoAPI.YAPI;
import com.yoctopuce.YoctoAPI.YAPI_Exception;
import com.yoctopuce.YoctoAPI.YModule;

public class Inventory extends Activity
{
    @Override
    public void onCreate(Bundle savedInstanceState)
    {
        super.onCreate(savedInstanceState);
        setContentView(R.layout.inventory);
    }

    public void refreshInventory(View view)
    {
        LinearLayout layout = (LinearLayout) findViewById(R.id.inventoryList);
        layout.removeAllViews();

        try {
            YAPI.UpdateDeviceList();
            YModule module = YModule.FirstModule();
            while (module != null) {
                String line = module.get_serialNumber() + " (" + module.get_productName() +
                ")";

                TextView tx = new TextView(this);
                tx.setText(line);
                tx.setTextSize(TypedValue.COMPLEX_UNIT_SP, 20);
                layout.addView(tx);
                module = module.nextModule();
            }
        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
    }

    @Override
    protected void onStart()
    {
        super.onStart();
        try {
            YAPI.EnableUSBHost(this);
            YAPI.RegisterHub("usb");
        } catch (YAPI_Exception e) {
            e.printStackTrace();
        }
        refreshInventory(null);
    }

    @Override
    protected void onStop()
    {
        super.onStop();
        YAPI.FreeAPI();
    }
}
```

16.7. Error handling

When you implement a program which must interact with USB modules, you cannot disregard error handling. Inevitably, there will be a time when a user will have unplugged the device, either before running the software, or even while the software is running. The Yoctopuce library is designed to help you support this kind of behavior, but your code must nevertheless be conceived to interpret in the best possible way the errors indicated by the library.

The simplest way to work around the problem is the one used in the short examples provided in this chapter: before accessing a module, check that it is online with the `isOnline` function, and then hope that it will stay so during the fraction of a second necessary for the following code lines to run. This method is not perfect, but it can be sufficient in some cases. You must however be aware that you cannot completely exclude an error which would occur after the call to `isOnline` and which could crash the software.

In the Java API for Android, error handling is implemented with exceptions. Therefore you must catch and handle correctly all exceptions that might be thrown by the API if you do not want your software to crash soon as you unplug a device.

17. Advanced programming

The preceding chapters have introduced, in each available language, the basic programming functions which can be used with your Yocto-PowerRelay module. This chapter presents in a more generic manner a more advanced use of your module. Examples are provided in the language which is the most popular among Yoctopuce customers, that is C#. Nevertheless, you can find complete examples illustrating the concepts presented here in the programming libraries of each language.

To remain as concise as possible, examples provided in this chapter do not perform any error handling. Do not copy them "as is" in a production application.

17.1. Event programming

The methods to manage Yoctopuce modules which we presented to you in preceding chapters were polling functions, consisting in permanently asking the API if something had changed. While easy to understand, this programming technique is not the most efficient, nor the most reactive. Therefore, the Yoctopuce programming API also provides an event programming model. This technique consists in asking the API to signal by itself the important changes as soon as they are detected. Each time a key parameter is modified, the API calls a callback function which you have defined in advance.

Detecting module arrival and departure

Hot-plug management is important when you work with USB modules because, sooner or later, you will have to connect or disconnect a module when your application is running. The API is designed to manage module unexpected arrival or departure in a transparent way. But your application must take this into account if it wants to avoid pretending to use a disconnected module.

Event programming is particularly useful to detect module connection/disconnection. Indeed, it is simpler to be told of new connections rather than to have to permanently list the connected modules to deduce which ones just arrived and which ones left. To be warned as soon as a module is connected, you need three pieces of code.

The callback

The callback is the function which is called each time a new Yoctopuce module is connected. It takes as parameter the relevant module.

```
static void deviceArrival(YModule m)
{
    Console.WriteLine("New module : " + m.get_serialNumber());
}
```

Initialization

You must then tell the API that it must call the callback when a new module is connected.

```
YAPI.RegisterDeviceArrivalCallback(deviceArrival);
```

Note that if modules are already connected when the callback is registered, the callback is called for each of the already connected modules.

Triggering callbacks

A classis issue of callback programming is that these callbacks can be triggered at any time, including at times when the main program is not ready to receive them. This can have undesired side effects, such as dead-locks and other race conditions. Therefore, in the Yoctopuce API, module arrival/departure callbacks are called only when the `UpdateDeviceList()` function is running. You only need to call `UpdateDeviceList()` at regular intervals from a timer or from a specific thread to precisely control when the calls to these callbacks happen:

```
// waiting loop managing callbacks
while (true)
{
    // module arrival / departure callback
    YAPI.UpdateDeviceList(ref errmsg);
    // non active waiting time managing other callbacks
    YAPI.Sleep(500, ref errmsg);
}
```

In a similar way, it is possible to have a callback when a module is disconnected. You can find a complete example implemented in your favorite programming language in the *Examples/Prog-EventBased* directory of the corresponding library.

Be aware that in most programming languages, callbacks must be global procedures, and not methods. If you wish for the callback to call the method of an object, define your callback as a global procedure which then calls your method.

18. Firmware Update

There are multiples way to update the firmware of a Yoctopuce module..

18.1. The VirtualHub or the YoctoHub

It is possible to update the firmware directly from the web interface of the VirtualHub or the YoctoHub. The configuration panel of the module has an "upgrade" button to start a wizard that will guide you through the firmware update procedure.

In case the firmware update fails for any reason, and the module does no start anymore, simply unplug the module then plug it back while maintaining the *Yocto-button* down. The module will boot in "firmware update" mode and will appear in the VirtualHub interface below the module list.

18.2. The command line library

All the command line tools can update Yoctopuce modules thanks to the `downloadAndUpdate` command. The module selection mechanism works like for a traditional command. The `[target]` is the name of the module that you want to update. You can also use the "any" or "all" aliases, or even a name list, where the names are separated by commas, without spaces.

```
C:\>Executable [options] [target] command [parameters]
```

The following example updates all the Yoctopuce modules connected by USB.

```
C:\>YModule all downloadAndUpdate
ok: Yocto-PowerRelay RELAYHI1-266C8(rev=15430) is up to date.
ok: 0 / 0 hubs in 0.000000s.
ok: 0 / 0 shields in 0.000000s.
ok: 1 / 1 devices in 0.130000s 0.130000s per device.
ok: All devices are now up to date.
C:\>
```

18.3. The Android application Yocto-Firmware

You can update your module firmware from your Android phone or tablet with the [Yocto-Firmware](#) application. This application lists all the Yoctopuce modules connected by USB and checks if a more recent firmware is available on www.yoctopuce.com. If a more recent firmware is available, you can

update the module. The application is responsible for downloading and installing the new firmware while preserving the module parameters.

Please note: while the firmware is being updated, the module restarts several times. Android interprets a USB device reboot as a disconnection and reconnection of the USB device and asks the authorization to use the USB port again. The user must click on *OK* for the update process to end successfully.

18.4. Updating the firmware with the programming library

If you need to integrate firmware updates in your application, the libraries offer you an API to update your modules.¹

Saving and restoring parameters

The `get_allSettings()` method returns a binary buffer enabling you to save a module persistent parameters. This function is very useful to save the network configuration of a YoctoHub for example.

```
YWireless wireless = YWireless.FindWireless("reference");
YModule m = wireless.get_module();
byte[] default_config = m.get_allSettings();
saveFile("default.bin", default_config);
...
```

You can then apply these parameters to other modules with the `set_allSettings()` method.

```
byte[] default_config = loadFile("default.bin");
YModule m = YModule.FirstModule();
while (m != null) {
    if (m.get_productName() == "YoctoHub-Wireless") {
        m.set_allSettings(default_config);
    }
    m = m.next();
}
```

Finding the correct firmware

The first step to update a Yoctopuce module is to find which firmware you must use. The `checkFirmware(path, onlynew)` method of the `YModule` object does exactly this. The method checks that the firmware given as argument (`path`) is compatible with the module. If the `onlynew` parameter is set, this method checks that the firmware is more recent than the version currently used by the module. When the file is not compatible (or if the file is older than the installed version), this method returns an empty string. In the opposite, if the file is valid, the method returns a file access path.

The following piece of code checks that the `c:\tmp\METEOMK1.17328.byn` is compatible with the module stored in the `m` variable .

```
YModule m = YModule.FirstModule();
...
...
string path = "c:\\tmp\\METEOMK1.17328.byn";
string newfirm = m.checkFirmware(path, false);
if (newfirm != "") {
    Console.WriteLine("firmware " + newfirm + " is compatible");
}
...
```

¹ The JavaScript, Node.js, and PHP libraries do not yet allow you to update the modules. These functions will be available in a next build.

The argument can be a directory (instead of a file). In this case, the method checks all the files of the directory recursively and returns the most recent compatible firmware. The following piece of code checks whether there is a more recent firmware in the `c:\tmp\` directory.

```
YModule m = YModule.FirstModule();
...
...
string path = "c:\\tmp";
string newfirm = m.checkFirmware(path, true);
if (newfirm != "") {
    Console.WriteLine("firmware " + newfirm + " is compatible and newer");
}
...
```

You can also give the `"www.yoctopuce.com"` string as argument to check whether there is a more recent published firmware on Yoctopuce's web site. In this case, the method returns the firmware URL. You can use this URL to download the firmware on your disk or use this URL when updating the firmware (see below). Obviously, this possibility works only if your machine is connected to Internet.

```
YModule m = YModule.FirstModule();
...
...
string url = m.checkFirmware("www.yoctopuce.com", true);
if (url != "") {
    Console.WriteLine("new firmware is available at " + url );
}
...
```

Updating the firmware

A firmware update can take several minutes. That is why the update process is run as a background task and is driven by the user code thanks to the `YFirmwareUpdate` class.

To update a Yoctopuce module, you must obtain an instance of the `YFirmwareUpdate` class with the `updateFirmware` method of a `YModule` object. The only parameter of this method is the *path* of the firmware that you want to install. This method does not immediately start the update, but returns a `YFirmwareUpdate` object configured to update the module.

```
string newfirm = m.checkFirmware("www.yoctopuce.com", true);
....
YFirmwareUpdate fw_update = m.updateFirmware(newfirm);
```

The `startUpdate()` method starts the update as a background task. This background task automatically takes care of

1. saving the module parameters
2. restarting the module in "update" mode
3. updating the firmware
4. starting the module with the new firmware version
5. restoring the parameters

The `get_progress()` and `get_progressMessage()` methods enable you to follow the progression of the update. `get_progress()` returns the progression as a percentage (100 = update complete). `get_progressMessage()` returns a character string describing the current operation (deleting, writing, rebooting, ...). If the `get_progress` method returns a negative value, the update process failed. In this case, the `get_progressMessage()` returns an error message.

The following piece of code starts the update and displays the progress on the standard output.

```
YFirmwareUpdate fw_update = m.updateFirmware(newfirm);
....
int status = fw_update.startUpdate();
while (status < 100 && status >= 0) {
```

```

int newstatus = fw_update.get_progress();
if (newstatus != status) {
    Console.WriteLine(status + "% "
        + fw_update.get_progressMessage());
}
YAPI.Sleep(500, ref errmsg);
status = newstatus;
}

if (status < 0) {
    Console.WriteLine("Firmware Update failed: "
        + fw_update.get_progressMessage());
} else {
    Console.WriteLine("Firmware Updated Successfully!");
}

```

An Android characteristic

You can update a module firmware using the Android library. However, for modules connected by USB, Android asks the user to authorize the application to access the USB port.

During firmware update, the module restarts several times. Android interprets a USB device reboot as a disconnection and a reconnection to the USB port, and prevents all USB access as long as the user has not closed the pop-up window. The user has to click on *OK* for the update process to continue correctly. **You cannot update a module connected by USB to an Android device without having the user interacting with the device.**

18.5. The "update" mode

If you want to erase all the parameters of a module or if your module does not start correctly anymore, you can install a firmware from the "update" mode.

To force the module to work in "update" mode, disconnect it, wait a few seconds, and reconnect it while maintaining the *Yocto-button* down. This will restart the module in "update" mode. This update mode is protected against corruptions and is always available.

In this mode, the module is not detected by the `YModule` objects anymore. To obtain the list of connected modules in "update" mode, you must use the `YAPI.GetAllBootLoaders()` function. This function returns a character string array with the serial numbers of the modules in "update" mode.

```
List<string> allBootLoader = YAPI.GetAllBootLoaders();
```

The update process is identical to the standard case (see the preceding section), but you must manually instantiate the `YFirmwareUpdate` object instead of calling `module.updateFirmware()`. The constructor takes as argument three parameters: the module serial number, the path of the firmware to be installed, and a byte array with the parameters to be restored at the end of the update (or `null` to restore default parameters).

```

YFirmwareUpdate fw_update;
fw_update = new YFirmwareUpdate(allBootLoader[0], newfirm, null);
int status = fw_update.startUpdate();
.....

```

19. Using with unsupported languages

Yoctopuce modules can be driven from most common programming languages. New languages are regularly added, depending on the interest expressed by Yoctopuce product users. Nevertheless, some languages are not, and will never be, supported by Yoctopuce. There can be several reasons for this: compilers which are not available anymore, unadapted environments, etc.

However, there are alternative methods to access Yoctopuce modules from an unsupported programming language.

19.1. Command line

The easiest method to drive Yoctopuce modules from an unsupported programming language is to use the command line API through system calls. The command line API is in fact made of a group of small executables which are easy to call. Their output is also easy to analyze. As most programming languages allow you to make system calls, the issue is solved with a few lines of code.

However, if the command line API is the easiest solution, it is neither the fastest nor the most efficient. For each call, the executable must initialize its own API and make an inventory of USB connected modules. This requires about one second per call.

19.2. VirtualHub and HTTP GET

The *VirtualHub* is available on almost all current platforms. It is generally used as a gateway to provide access to Yoctopuce modules from languages which prevent direct access to hardware layers of a computer (JavaScript, PHP, Java, ...).

In fact, the *VirtualHub* is a small web server able to route HTTP requests to Yoctopuce modules. This means that if you can make an HTTP request from your programming language, you can drive Yoctopuce modules, even if this language is not officially supported.

REST interface

At a low level, the modules are driven through a REST API. Thus, to control a module, you only need to perform appropriate requests on the *VirtualHub*. By default, the *VirtualHub* HTTP port is 4444.

An important advantage of this technique is that preliminary tests are very easy to implement. You only need a *VirtualHub* and a simple web browser. If you copy the following URL in your preferred browser, while the *VirtualHub* is running, you obtain the list of the connected modules.

```
http://127.0.0.1:4444/api/services/whitePages.txt
```

Note that the result is displayed as text, but if you request *whitePages.xml*, you obtain an XML result. Likewise, *whitePages.json* allows you to obtain a JSON result. The *html* extension even allows you to display a rough interface where you can modify values in real time. The whole REST API is available in these different formats.

Driving a module through the REST interface

Each Yoctopuce module has its own REST interface, available in several variants. Let us imagine a Yocto-PowerRelay with the *RELAYHI1-12345* serial number and the *myModule* logical name. The following URL allows you to know the state of the module.

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/api/module.txt
```

You can naturally also use the module logical name rather than its serial number.

```
http://127.0.0.1:4444/byName/myModule/api/module.txt
```

To retrieve the value of a module property, simply add the name of the property below *module*. For example, if you want to know the signposting led luminosity, send the following request:

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/api/module/luminosity
```

To change the value of a property, modify the corresponding attribute. Thus, to modify the luminosity, send the following request:

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/api/module?luminosity=100
```

Driving the module functions through the REST interface

The module functions can be manipulated in the same way. To know the state of the relay1 function, build the following URL:

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/api/relay1.txt
```

Note that if you can use logical names for the modules instead of their serial number, you cannot use logical names for functions. Only hardware names are authorized to access functions.

You can retrieve a module function attribute in a way rather similar to that used with the modules. For example:

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/api/relay1/logicalName
```

Rather logically, attributes can be modified in the same manner.

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/api/relay1?logicalName=myFunction
```

You can find the list of available attributes for your Yocto-PowerRelay at the beginning of the *Programming* chapter.

Accessing Yoctopuce data logger through the REST interface

This section only applies to devices with a built-in data logger.

The preview of all recorded data streams can be retrieved in JSON format using the following URL:

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/dataLogger.json
```

Individual measures for any given stream can be obtained by appending the desired function identifier as well as start time of the stream:

```
http://127.0.0.1:4444/bySerial/RELAYHI1-12345/dataLogger.json?id=relay1&utc=1389801080
```

19.3. Using dynamic libraries

The low level Yoctopuce API is available under several formats of dynamic libraries written in C. The sources are available with the C++ API. If you use one of these low level libraries, you do not need the *VirtualHub* anymore.

Filename	Platform
libyapi.dylib	Max OS X
libyapi-amd64.so	Linux Intel (64 bits)
libyapi-armel.so	Linux ARM EL
libyapi-armhf.so	Linux ARM HL
libyapi-i386.so	Linux Intel (32 bits)
yapi64.dll	Windows (64 bits)
yapi.dll	Windows (32 bits)

These dynamic libraries contain all the functions necessary to completely rebuild the whole high level API in any language able to integrate these libraries. This chapter nevertheless restrains itself to describing basic use of the modules.

Driving a module

The three essential functions of the low level API are the following:

```
int yapiInitAPI(int connection_type, char *errmsg);
int yapiUpdateDeviceList(int forceupdate, char *errmsg);
int yapiHTTPRequest(char *device, char *request, char* buffer, int buffsize, int *fullsize,
char *errmsg);
```

The *yapiInitAPI* function initializes the API and must be called once at the beginning of the program. For a USB type connection, the *connection_type* parameter takes value 1. The *errmsg* parameter must point to a 255 character buffer to retrieve a potential error message. This pointer can also point to *null*. The function returns a negative integer in case of error, zero otherwise.

The *yapiUpdateDeviceList* manages the inventory of connected Yoctopuce modules. It must be called at least once. To manage hot plug and detect potential newly connected modules, this function must be called at regular intervals. The *forceupdate* parameter must take value 1 to force a hardware scan. The *errmsg* parameter must point to a 255 character buffer to retrieve a potential error message. This pointer can also point to *null*. The function returns a negative integer in case of error, zero otherwise.

Finally, the *yapiHTTPRequest* function sends HTTP requests to the module REST API. The *device* parameter contains the serial number or the logical name of the module which you want to reach. The *request* parameter contains the full HTTP request (including terminal line breaks). *buffer* points to a character buffer long enough to contain the answer. *buffsize* is the size of the buffer. *fullsize* is a pointer to an integer to which will be assigned the actual size of the answer. The *errmsg* parameter must point to a 255 character buffer to retrieve a potential error message. This pointer can also point to *null*. The function returns a negative integer in case of error, zero otherwise.

The format of the requests is the same as the one described in the *VirtualHub et HTTP GET* section. All the character strings used by the API are strings made of 8-bit characters: Unicode and UTF8 are not supported.

The result returned in the buffer variable respects the HTTP protocol. It therefore includes an HTTP header. This header ends with two empty lines, that is a sequence of four ASCII characters 13, 10, 13, 10.

Here is a sample program written in pascal using the *yapi.dll* DLL to read and then update the luminosity of a module.

```
// Dll functions import
function yapiInitAPI(mode:integer;
                    errmsg : pansichar):integer;cdecl;
                    external 'yapi.dll' name 'yapiInitAPI';
function yapiUpdateDeviceList(force:integer;errmsg : pansichar):integer;cdecl;
                    external 'yapi.dll' name 'yapiUpdateDeviceList';
function yapiHTTPRequest(device:pansichar;url:pansichar; buffer:pansichar;
                        buffsize:integer;var fullsize:integer;
                        errmsg : pansichar):integer;cdecl;
                        external 'yapi.dll' name 'yapiHTTPRequest';

var
    errmsgBuffer : array [0..256] of ansichar;
    dataBuffer   : array [0..1024] of ansichar;
    errmsg,data   : pansichar;
    fullsize,p    : integer;

const
    serial       = 'RELAYHI1-12345';
    getValue = 'GET /api/module/luminosity HTTP/1.1'#13#10#13#10;
    setValue = 'GET /api/module?luminosity=100 HTTP/1.1'#13#10#13#10;

begin
    errmsg := @errmsgBuffer;
    data := @dataBuffer;
    // API initialization
    if(yapiInitAPI(1,errmsg)<0) then
        begin
            writeln(errmsg);
            halt;
        end;

    // forces a device inventory
    if( yapiUpdateDeviceList(1,errmsg)<0) then
        begin
            writeln(errmsg);
            halt;
        end;

    // requests the module luminosity
    if (yapiHTTPRequest(serial,getValue,data,sizeof(dataBuffer),fullsize,errmsg)<0) then
        begin
            writeln(errmsg);
            halt;
        end;

    // searches for the HTTP header end
    p := pos(#13#10#13#10,data);

    // displays the response minus the HTTP header
    writeln(copy(data,p+4,length(data)-p-3));

    // changes the luminosity
    if (yapiHTTPRequest(serial,setValue,data,sizeof(dataBuffer),fullsize,errmsg)<0) then
        begin
            writeln(errmsg);
            halt;
        end;

end.
```

Module inventory

To perform an inventory of Yoctopuce modules, you need two functions from the dynamic library:

```
int yapiGetAllDevices(int *buffer,int maxsize,int *neededsize,char *errmsg);
int yapiGetDeviceInfo(int devdesc,yDeviceSt *infos, char *errmsg);
```

The *yapiGetAllDevices* function retrieves the list of all connected modules as a list of handles. *buffer* points to a 32-bit integer array which contains the returned handles. *maxsize* is the size in bytes of the buffer. To *neededsize* is assigned the necessary size to store all the handles. From this, you can deduce either the number of connected modules or that the input buffer is too small. The *errmsg*

parameter must point to a 255 character buffer to retrieve a potential error message. This pointer can also point to *null*. The function returns a negative integer in case of error, zero otherwise.

The *yapiGetDeviceInfo* function retrieves the information related to a module from its handle. *devdesc* is a 32-bit integer representing the module and which was obtained through *yapiGetAllDevices*. *infos* points to a data structure in which the result is stored. This data structure has the following format:

Name	Type	Size (bytes)	Description
vendorid	int	4	Yoctopuce USB ID
deviceid	int	4	Module USB ID
devrelease	int	4	Module version
nbinbterfaces	int	4	Number of USB interfaces used by the module
manufacturer	char[]	20	Yoctopuce (null terminated)
productname	char[]	28	Model (null terminated)
serial	char[]	20	Serial number (null terminated)
logicalname	char[]	20	Logical name (null terminated)
firmware	char[]	22	Firmware version (null terminated)
beacon	byte	1	Beacon state (0/1)

The *errmsg* parameter must point to a 255 character buffer to retrieve a potential error message.

Here is a sample program written in pascal using the *yapi.dll* DLL to list the connected modules.

```
// device description structure
type yDeviceSt = packed record
  vendorid      : word;
  deviceid      : word;
  devrelease    : word;
  nbinbterfaces : word;
  manufacturer  : array [0..19] of ansichar;
  productname   : array [0..27] of ansichar;
  serial        : array [0..19] of ansichar;
  logicalname    : array [0..19] of ansichar;
  firmware      : array [0..21] of ansichar;
  beacon        : byte;
end;

// Dll function import
function yapiInitAPI(mode:integer;
  errmsg : pansichar):integer;cdecl;
  external 'yapi.dll' name 'yapiInitAPI';

function yapiUpdateDeviceList(force:integer;errmsg : pansichar):integer;cdecl;
  external 'yapi.dll' name 'yapiUpdateDeviceList';

function yapiGetAllDevices( buffer:pointer;
  maxsize:integer;
  var neededsize:integer;
  errmsg : pansichar):integer; cdecl;
  external 'yapi.dll' name 'yapiGetAllDevices';

function apiGetDeviceInfo(d:integer; var infos:yDeviceSt;
  errmsg : pansichar):integer; cdecl;
  external 'yapi.dll' name 'yapiGetDeviceInfo';

var
  errmsgBuffer : array [0..256] of ansichar;
  dataBuffer    : array [0..127] of integer; // max of 128 USB devices
  errmsg,data   : pansichar;
  neededsize,i  : integer;
  devinfos      : yDeviceSt;

begin
  errmsg := @errmsgBuffer;

  // API initialization
  if(yapiInitAPI(1,errmsg)<0) then
    begin
      writeln(errmsg);
```

```

    halt;
end;

// forces a device inventory
if( yapiUpdateDeviceList(1,errmsg)<0) then
begin
    writeln(errmsg);
    halt;
end;

// loads all device handles into dataBuffer
if yapiGetAllDevices(@dataBuffer,sizeof(dataBuffer),neededsize,errmsg)<0 then
begin
    writeln(errmsg);
    halt;
end;

// gets device info from each handle
for i:=0 to neededsize div sizeof(integer)-1 do
begin
    if (apiGetDeviceInfo(dataBuffer[i], devinfos, errmsg)<0) then
    begin
        writeln(errmsg);
        halt;
    end;
    writeln(pansichar(@devinfos.serial)+' ('+pansichar(@devinfos.productname)+' ');
end;

end.

```

VB6 and yapi.dll

Each entry point from the yapi.dll is duplicated. You will find one regular C-decl version and one Visual Basic 6 compatible version, prefixed with `vb6_`.

19.4. Porting the high level library

As all the sources of the Yoctopuce API are fully provided, you can very well port the whole API in the language of your choice. Note, however, that a large portion of the API source code is automatically generated.

Therefore, it is not necessary for you to port the complete API. You only need to port the *yocto_api* file and one file corresponding to a function, for example *yocto_relay*. After a little additional work, Yoctopuce is then able to generate all other files. Therefore, we highly recommend that you contact Yoctopuce support before undertaking to port the Yoctopuce library in another language. Collaborative work is advantageous to both parties.

20. High-level API Reference

This chapter summarizes the high-level API functions to drive your Yocto-PowerRelay. Syntax and exact type names may vary from one language to another, but, unless otherwise stated, all the functions are available in every language. For detailed information regarding the types of arguments and return values for a given language, refer to the definition file for this language (`yocto_api.*` as well as the other `yocto_*` files that define the function interfaces).

For languages which support exceptions, all of these functions throw exceptions in case of error by default, rather than returning the documented error value for each function. This is by design, to facilitate debugging. It is however possible to disable the use of exceptions using the `yDisableExceptions()` function, in case you prefer to work with functions that return error values.

This chapter does not repeat the programming concepts described earlier, in order to stay as concise as possible. In case of doubt, do not hesitate to go back to the chapter describing in details all configurable attributes.

20.1. General functions

These general functions should be used to initialize and configure the Yoctopuce library. In most cases, a simple call to function `yRegisterHub()` should be enough. The module-specific functions `yFind...()` or `yFirst...()` should then be used to retrieve an object that provides interaction with the module.

In order to use the functions described here, you should include:

js	<code><script type='text/javascript' src='yocto_api.js'></script></code>
cpp	<code>#include "yocto_api.h"</code>
m	<code>#import "yocto_api.h"</code>
pas	<code>uses yocto_api;</code>
vb	<code>yocto_api.vb</code>
cs	<code>yocto_api.cs</code>
java	<code>import com.yoctopuce.YoctoAPI.YModule;</code>
uwp	<code>import com.yoctopuce.YoctoAPI.YModule;</code>
py	<code>from yocto_api import *</code>
php	<code>require_once('yocto_api.php');</code>
es	in HTML: <code><script src='../lib/yocto_api.js'></script></code> in node.js: <code>require('yoctolib-es2017/yocto_api.js');</code>

Global functions

yCheckLogicalName(name)

Checks if a given string is valid as logical name for a module or a function.

yClearHTTPCallbackCacheDir(bool_removeFiles)

Disables the HTTP callback cache.

yDisableExceptions()

Disables the use of exceptions to report runtime errors.

yEnableExceptions()

Re-enables the use of exceptions for runtime error handling.

yEnableUSBHost(osContext)

This function is used only on Android.

yFreeAPI()

Frees dynamically allocated memory blocks used by the Yoctopuce library.

yGetAPIVersion()

Returns the version identifier for the Yoctopuce library in use.

yGetTickCount()

Returns the current value of a monotone millisecond-based time counter.

yHandleEvents(errmsg)

Maintains the device-to-library communication channel.

yInitAPI(mode, errmsg)

Initializes the Yoctopuce programming library explicitly.

yPreregisterHub(url, errmsg)

Fault-tolerant alternative to `RegisterHub()`.

yRegisterDeviceArrivalCallback(arrivalCallback)

Register a callback function, to be called each time a device is plugged.

yRegisterDeviceRemovalCallback(removalCallback)

Register a callback function, to be called each time a device is unplugged.

yRegisterHub(url, errmsg)

Setup the Yoctopuce library to use modules connected on a given machine.

yRegisterHubDiscoveryCallback(hubDiscoveryCallback)

Register a callback function, to be called each time an Network Hub send an SSDP message.

yRegisterLogFunction(logfun)

Registers a log callback function.

ySelectArchitecture(arch)

Select the architecture or the library to be loaded to access to USB.

ySetDelegate(object)

(Objective-C only) Register an object that must follow the protocol YDeviceHotPlug.

ySetHTTPCallbackCacheDir(str_directory)

Enables the HTTP callback cache.

ySetTimeout(callback, ms_timeout, args)

Invoke the specified callback function after a given timeout.

ySetUSBPacketAckMs(pktAckDelay)

Enables the acknowledge of every USB packet received by the Yoctopuce library.

ySleep(ms_duration, errmsg)

Pauses the execution flow for a specified duration.

yTestHub(url, mstimeout, errmsg)

Test if the hub is reachable.

yTriggerHubDiscovery(errmsg)

Force a hub discovery, if a callback as been registered with yRegisterHubDiscoveryCallback it will be called for each net work hub that will respond to the discovery.

yUnregisterHub(url)

Setup the Yoctopuce library to no more use modules connected on a previously registered machine with RegisterHub.

yUpdateDeviceList(errmsg)

Triggers a (re)detection of connected Yoctopuce modules.

yUpdateDeviceList_async(callback, context)

Triggers a (re)detection of connected Yoctopuce modules.

YAPI.CheckLogicalName() yCheckLogicalName()

YAPI

Checks if a given string is valid as logical name for a module or a function.

js	function yCheckLogicalName (name)
cpp	bool yCheckLogicalName (const string& name)
m	+(BOOL) CheckLogicalName :(NSString *) name
pas	function yCheckLogicalName (name : string): boolean
vb	function yCheckLogicalName (ByVal name As String) As Boolean
cs	bool CheckLogicalName (string name)
java	boolean CheckLogicalName (String name)
uwp	bool CheckLogicalName (string name)
py	def CheckLogicalName (name)
php	function yCheckLogicalName (\$name)
es	function CheckLogicalName (name)

A valid logical name has a maximum of 19 characters, all among A . . Z, a . . z, 0 . . 9, __, and - . If you try to configure a logical name with an incorrect string, the invalid characters are ignored.

Parameters :

name a string containing the name to check.

Returns :

true if the name is valid, false otherwise.

YAPI.ClearHTTPCallbackCacheDir() yClearHTTPCallbackCacheDir()

YAPI

Disables the HTTP callback cache.

```
php function yClearHTTPCallbackCacheDir( $bool_removeFiles)
```

This method disables the HTTP callback cache, and can additionally cleanup the cache directory.

Parameters :

bool_removeFiles True to clear the content of the cache.

Returns :

nothing.

YAPI.DisableExceptions() yDisableExceptions()

YAPI

Disables the use of exceptions to report runtime errors.

js	function yDisableExceptions ()
cpp	void yDisableExceptions ()
m	+(void) DisableExceptions
pas	procedure yDisableExceptions ()
vb	procedure yDisableExceptions ()
cs	void DisableExceptions ()
py	def DisableExceptions ()
php	function yDisableExceptions ()
es	function DisableExceptions ()

When exceptions are disabled, every function returns a specific error value which depends on its type and which is documented in this reference manual.

YAPI.EnableExceptions() yEnableExceptions()

YAPI

Re-enables the use of exceptions for runtime error handling.

js	function yEnableExceptions ()
cpp	void yEnableExceptions ()
m	+(void) EnableExceptions
pas	procedure yEnableExceptions ()
vb	procedure yEnableExceptions ()
cs	void EnableExceptions ()
py	def EnableExceptions ()
php	function yEnableExceptions ()
es	function EnableExceptions ()

Be aware that when exceptions are enabled, every function that fails triggers an exception. If the exception is not caught by the user code, it either fires the debugger or aborts (i.e. crash) the program. On failure, throws an exception or returns a negative error code.

YAPI.EnableUSBHost() yEnableUSBHost()

YAPI

This function is used only on Android.

```
java void EnableUSBHost( Object osContext)
```

Before calling `yRegisterHub("usb")` you need to activate the USB host port of the system. This function takes as argument, an object of class `android.content.Context` (or any subclass). It is not necessary to call this function to reach modules through the network.

Parameters :

osContext an object of class `android.content.Context` (or any subclass).

YAPI.FreeAPI() yFreeAPI()

YAPI

Frees dynamically allocated memory blocks used by the Yoctopuce library.

js	function yFreeAPI ()
cpp	void yFreeAPI ()
m	+(void) FreeAPI
pas	procedure yFreeAPI ()
vb	procedure yFreeAPI ()
cs	void FreeAPI ()
java	void FreeAPI ()
uwp	void FreeAPI ()
py	def FreeAPI ()
php	function yFreeAPI ()
es	function FreeAPI ()

It is generally not required to call this function, unless you want to free all dynamically allocated memory blocks in order to track a memory leak for instance. You should not call any other library function after calling `yFreeAPI( )`, or your program will crash.

YAPI.GetAPIVersion() yGetAPIVersion()

YAPI

Returns the version identifier for the Yoctopuce library in use.

js	function yGetAPIVersion ()
cpp	string yGetAPIVersion ()
m	+(NSString*) GetAPIVersion
pas	function yGetAPIVersion (): string
vb	function yGetAPIVersion () As String
cs	String GetAPIVersion ()
java	String GetAPIVersion ()
uwp	string GetAPIVersion ()
py	def GetAPIVersion ()
php	function yGetAPIVersion ()
es	function GetAPIVersion ()

The version is a string in the form "Major.Minor.Build", for instance "1.01.5535". For languages using an external DLL (for instance C#, VisualBasic or Delphi), the character string includes as well the DLL version, for instance "1.01.5535 (1.01.5439)".

If you want to verify in your code that the library version is compatible with the version that you have used during development, verify that the major number is strictly equal and that the minor number is greater or equal. The build number is not relevant with respect to the library compatibility.

Returns :

a character string describing the library version.

YAPI.GetTickCount() yGetTickCount()

YAPI

Returns the current value of a monotone millisecond-based time counter.

js	function yGetTickCount ()
cpp	u64 yGetTickCount ()
m	+(u64) GetTickCount
pas	function yGetTickCount (): u64
vb	function yGetTickCount () As Long
cs	ulong GetTickCount ()
java	long GetTickCount ()
uwp	ulong GetTickCount ()
py	def GetTickCount ()
php	function yGetTickCount ()
es	function GetTickCount ()

This counter can be used to compute delays in relation with Yoctopuce devices, which also uses the millisecond as timebase.

Returns :

a long integer corresponding to the millisecond counter.

YAPI.HandleEvents() yHandleEvents()

Maintains the device-to-library communication channel.

js	function yHandleEvents (errmsg)
cpp	YRETCODE yHandleEvents (string& errmsg)
m	+(YRETCODE) HandleEvents :(NSError**) errmsg
pas	function yHandleEvents (var errmsg : string): integer
vb	function yHandleEvents (ByRef errmsg As String) As YRETCODE
cs	YRETCODE HandleEvents (ref string errmsg)
java	int HandleEvents ()
uwp	async Task<int> HandleEvents ()
py	def HandleEvents (errmsg =None)
php	function yHandleEvents (&\$ errmsg)
es	function HandleEvents (errmsg)

If your program includes significant loops, you may want to include a call to this function to make sure that the library takes care of the information pushed by the modules on the communication channels. This is not strictly necessary, but it may improve the reactivity of the library for the following commands.

This function may signal an error in case there is a communication problem while contacting a module.

Parameters :

errmsg a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.InitAPI() yInitAPI()

YAPI

Initializes the Yoctopuce programming library explicitly.

js	function yInitAPI (mode , errmsg)
cpp	YRETCODE yInitAPI (int mode , string& errmsg)
m	+(YRETCODE) InitAPI :(int) mode :(NSError**) errmsg
pas	function yInitAPI (mode : integer, var errmsg : string): integer
vb	function yInitAPI (ByVal mode As Integer, ByRef errmsg As String) As Integer
cs	int InitAPI (int mode , ref string errmsg)
java	int InitAPI (int mode)
uwp	async Task<int> InitAPI (int mode)
py	def InitAPI (mode , errmsg =None)
php	function yInitAPI (\$mode , & \$errmsg)
es	function InitAPI (mode , errmsg)

It is not strictly needed to call `yInitAPI()`, as the library is automatically initialized when calling `yRegisterHub()` for the first time.

When `Y_DETECT_NONE` is used as detection mode, you must explicitly use `yRegisterHub()` to point the API to the VirtualHub on which your devices are connected before trying to access them.

Parameters :

mode an integer corresponding to the type of automatic device detection to use. Possible values are `Y_DETECT_NONE`, `Y_DETECT_USB`, `Y_DETECT_NET`, and `Y_DETECT_ALL`.

errmsg a string passed by reference to receive any error message.

Returns :

`YAPI_SUCCESS` when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.PreregisterHub() yPreregisterHub()

Fault-tolerant alternative to RegisterHub().

js	function yPreregisterHub (url , errmsg)
cpp	YRETCODE yPreregisterHub (const string& url , string& errmsg)
m	+(YRETCODE) PreregisterHub :(NSString *) url :(NSError**) errmsg
pas	function yPreregisterHub (url : string, var errmsg : string): integer
vb	function yPreregisterHub (ByVal url As String, ByRef errmsg As String) As Integer
cs	int PreregisterHub (string url , ref string errmsg)
java	int PreregisterHub (String url)
uwp	async Task<int> PreregisterHub (string url)
py	def PreregisterHub (url , errmsg =None)
php	function yPreregisterHub (\$url , &\$errmsg)
es	function PreregisterHub (url , errmsg)

This function has the same purpose and same arguments as RegisterHub(), but does not trigger an error when the selected hub is not available at the time of the function call. This makes it possible to register a network hub independently of the current connectivity, and to try to contact it only when a device is actively needed.

Parameters :

url a string containing either "usb", "callback" or the root URL of the hub to monitor
errmsg a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.RegisterDeviceArrivalCallback() yRegisterDeviceArrivalCallback()

YAPI

Register a callback function, to be called each time a device is plugged.

js	function yRegisterDeviceArrivalCallback (arrivalCallback)
cpp	void yRegisterDeviceArrivalCallback (yDeviceUpdateCallback arrivalCallback)
m	+(void) RegisterDeviceArrivalCallback :(yDeviceUpdateCallback) arrivalCallback
pas	procedure yRegisterDeviceArrivalCallback (arrivalCallback : yDeviceUpdateFunc)
vb	procedure yRegisterDeviceArrivalCallback (ByVal arrivalCallback As yDeviceUpdateFunc)
cs	void RegisterDeviceArrivalCallback (yDeviceUpdateFunc arrivalCallback)
java	void RegisterDeviceArrivalCallback (DeviceArrivalCallback arrivalCallback)
uwp	void RegisterDeviceArrivalCallback (DeviceUpdateHandler arrivalCallback)
py	def RegisterDeviceArrivalCallback (arrivalCallback)
php	function yRegisterDeviceArrivalCallback (\$arrivalCallback)
es	function RegisterDeviceArrivalCallback (arrivalCallback)

This callback will be invoked while yUpdateDeviceList is running. You will have to call this function on a regular basis.

Parameters :

arrivalCallback a procedure taking a YModule parameter, or null

YAPI.RegisterDeviceRemovalCallback() yRegisterDeviceRemovalCallback()

YAPI

Register a callback function, to be called each time a device is unplugged.

js	function yRegisterDeviceRemovalCallback (removalCallback)
cpp	void yRegisterDeviceRemovalCallback (yDeviceUpdateCallback removalCallback)
m	+(void) RegisterDeviceRemovalCallback :(yDeviceUpdateCallback) removalCallback
pas	procedure yRegisterDeviceRemovalCallback (removalCallback : yDeviceUpdateFunc)
vb	procedure yRegisterDeviceRemovalCallback (ByVal removalCallback As yDeviceUpdateFunc)
cs	void RegisterDeviceRemovalCallback (yDeviceUpdateFunc removalCallback)
java	void RegisterDeviceRemovalCallback (DeviceRemovalCallback removalCallback)
uwp	void RegisterDeviceRemovalCallback (DeviceUpdateHandler removalCallback)
py	def RegisterDeviceRemovalCallback (removalCallback)
php	function yRegisterDeviceRemovalCallback (\$removalCallback)
es	function RegisterDeviceRemovalCallback (removalCallback)

This callback will be invoked while yUpdateDeviceList is running. You will have to call this function on a regular basis.

Parameters :

removalCallback a procedure taking a YModule parameter, or null

YAPI.RegisterHub() yRegisterHub()

YAPI

Setup the Yoctopuce library to use modules connected on a given machine.

js	function yRegisterHub (url , errmsg)
cpp	YRETCODE yRegisterHub (const string& url , string& errmsg)
m	+(YRETCODE) RegisterHub :(NSString *) url :(NSError**) errmsg
pas	function yRegisterHub (url : string, var errmsg : string): integer
vb	function yRegisterHub (ByVal url As String, ByRef errmsg As String) As Integer
cs	int RegisterHub (string url , ref string errmsg)
java	int RegisterHub (String url)
uwp	async Task<int> RegisterHub (string url)
py	def RegisterHub (url , errmsg =None)
php	function yRegisterHub (\$url, &\$errmsg)
es	function RegisterHub (url , errmsg)

The parameter will determine how the API will work. Use the following values:

usb: When the **usb** keyword is used, the API will work with devices connected directly to the USB bus. Some programming languages such as Javascript, PHP, and Java don't provide direct access to USB hardware, so **usb** will not work with these. In this case, use a VirtualHub or a networked YoctoHub (see below).

x.x.x.x or **hostname**: The API will use the devices connected to the host with the given IP address or hostname. That host can be a regular computer running a VirtualHub, or a networked YoctoHub such as YoctoHub-Ethernet or YoctoHub-Wireless. If you want to use the VirtualHub running on your local computer, use the IP address 127.0.0.1.

callback: that keyword makes the API run in "HTTP Callback" mode. This is a special mode allowing to take control of Yoctopuce devices through a NAT filter when using a VirtualHub or a networked YoctoHub. You only need to configure your hub to call your server script on a regular basis. This mode is currently available for PHP and Node.JS only.

Be aware that only one application can use direct USB access at a given time on a machine. Multiple access would cause conflicts while trying to access the USB modules. In particular, this means that you must stop the VirtualHub software before starting an application that uses direct USB access. The workaround for this limitation is to setup the library to use the VirtualHub rather than direct USB access.

If access control has been activated on the hub, virtual or not, you want to reach, the URL parameter should look like:

`http://username:password@address:port`

You can call *RegisterHub* several times to connect to several machines.

Parameters :

url a string containing either "**usb**", "**callback**" or the root URL of the hub to monitor
errmsg a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.RegisterHubDiscoveryCallback() yRegisterHubDiscoveryCallback()

YAPI

Register a callback function, to be called each time an Network Hub send an SSDP message.

cpp	void yRegisterHubDiscoveryCallback (YHubDiscoveryCallback hubDiscoveryCallback)
m	+(void) RegisterHubDiscoveryCallback : (YHubDiscoveryCallback) hubDiscoveryCallback
pas	procedure yRegisterHubDiscoveryCallback (hubDiscoveryCallback : YHubDiscoveryCallback)
vb	procedure yRegisterHubDiscoveryCallback (ByVal hubDiscoveryCallback As YHubDiscoveryCallback)
cs	void RegisterHubDiscoveryCallback (YHubDiscoveryCallback hubDiscoveryCallback)
java	void RegisterHubDiscoveryCallback (HubDiscoveryCallback hubDiscoveryCallback)
uwp	async Task RegisterHubDiscoveryCallback (HubDiscoveryHandler hubDiscoveryCallback)
py	def RegisterHubDiscoveryCallback (hubDiscoveryCallback)

The callback has two string parameter, the first one contain the serial number of the hub and the second contain the URL of the network hub (this URL can be passed to RegisterHub). This callback will be invoked while yUpdateDeviceList is running. You will have to call this function on a regular basis.

Parameters :

hubDiscoveryCallback a procedure taking two string parameter, the serial

YAPI.RegisterLogFunction() yRegisterLogFunction()

YAPI

Registers a log callback function.

cpp	void yRegisterLogFunction (yLogFunction logfun)
m	+(void) RegisterLogFunction :(yLogCallback) logfun
pas	procedure yRegisterLogFunction (logfun : yLogFunc)
vb	procedure yRegisterLogFunction (ByVal logfun As yLogFunc)
cs	void RegisterLogFunction (yLogFunc logfun)
java	void RegisterLogFunction (LogCallback logfun)
uwp	void RegisterLogFunction (LogHandler logfun)
py	def RegisterLogFunction (logfun)

This callback will be called each time the API have something to say. Quite useful to debug the API.

Parameters :

logfun a procedure taking a string parameter, or null

YAPI.SelectArchitecture() ySelectArchitecture()

YAPI

Select the architecture or the library to be loaded to access to USB.

```
py def SelectArchitecture( arch)
```

By default, the Python library automatically detects the appropriate library to use. However, for Linux ARM, it not possible to reliably distinguish between a Hard Float (armhf) and a Soft Float (armel) install. For in this case, it is therefore recommended to manually select the proper architecture by calling `SelectArchitecture()` before any other call to the library.

Parameters :

arch A string containing the architecture to use. Possibles value are: "armhf","armel", "i386","x86_64","32bit", "64bit"

Returns :

nothing.

On failure, throws an exception.

YAPI.SetDelegate() ySetDelegate()

YAPI

(Objective-C only) Register an object that must follow the protocol YDeviceHotPlug.

```
m +(void) SetDelegate :(id) object
```

The methods `yDeviceArrival` and `yDeviceRemoval` will be invoked while `yUpdateDeviceList` is running. You will have to call this function on a regular basis.

Parameters :

object an object that must follow the protocol YAPIDelegate, or nil

YAPI.SetHTTPCallbackCacheDir() ySetHTTPCallbackCacheDir()

YAPI

Enables the HTTP callback cache.

```
php function ySetHTTPCallbackCacheDir( $str_directory)
```

When enabled, this cache reduces the quantity of data sent to the PHP script by 50% to 70%. To enable this cache, the method `ySetHTTPCallbackCacheDir()` must be called before any call to `yRegisterHub()`. This method takes in parameter the path of the directory used for saving data between each callback. This folder must exist and the PHP script needs to have write access to it. It is recommended to use a folder that is not published on the Web server since the library will save some data of Yoctopuce devices into this folder.

Note: This feature is supported by YoctoHub and VirtualHub since version 27750.

Parameters :

str_directory the path of the folder that will be used as cache.

Returns :

nothing.

On failure, throws an exception.

YAPI.SetTimeout() ySetTimeout()

YAPI

Invoke the specified callback function after a given timeout.

js	function ySetTimeout (callback , ms_timeout , args)
es	function SetTimeout (callback , ms_timeout , args)

This function behaves more or less like Javascript `setTimeout`, but during the waiting time, it will call `yHandleEvents` and `yUpdateDeviceList` periodically, in order to keep the API up-to-date with current devices.

Parameters :

- callback** the function to call after the timeout occurs. On Microsoft Internet Explorer, the callback must be provided as a string to be evaluated.
- ms_timeout** an integer corresponding to the duration of the timeout, in milliseconds.
- args** additional arguments to be passed to the callback function can be provided, if needed (not supported on Microsoft Internet Explorer).

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.SetUSBPacketAckMs() ySetUSBPacketAckMs()

YAPI

Enables the acknowledge of every USB packet received by the Yoctopuce library.

```
java void SetUSBPacketAckMs( int pktAckDelay)
```

This function allows the library to run on Android phones that tend to lose USB packets. By default, this feature is disabled because it doubles the number of packets sent and slows down the API considerably. Therefore, the acknowledge of incoming USB packets should only be enabled on phones or tablets that lose USB packets. A delay of 50 milliseconds is generally enough. In case of doubt, contact Yoctopuce support. To disable USB packets acknowledge, call this function with the value 0. Note: this feature is only available on Android.

Parameters :

pktAckDelay then number of milliseconds before the module

YAPI.Sleep() ySleep()

Pauses the execution flow for a specified duration.

js	function ySleep (ms_duration , errmsg)
cpp	YRETCODE ySleep (unsigned ms_duration , string& errmsg)
m	+(YRETCODE) Sleep :(unsigned) ms_duration :(NSError **) errmsg
pas	function ySleep (ms_duration : integer, var errmsg : string): integer
vb	function ySleep (ByVal ms_duration As Integer, ByRef errmsg As String) As Integer
cs	int Sleep (int ms_duration , ref string errmsg)
java	int Sleep (long ms_duration)
uwp	async Task<int> Sleep (ulong ms_duration)
py	def Sleep (ms_duration , errmsg =None)
php	function ySleep (\$ ms_duration , &\$ errmsg)
es	function Sleep (ms_duration , errmsg)

This function implements a passive waiting loop, meaning that it does not consume CPU cycles significantly. The processor is left available for other threads and processes. During the pause, the library nevertheless reads from time to time information from the Yoctopuce modules by calling `yHandleEvents()`, in order to stay up-to-date.

This function may signal an error in case there is a communication problem while contacting a module.

Parameters :

- ms_duration** an integer corresponding to the duration of the pause, in milliseconds.
- errmsg** a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.TestHub() yTestHub()

YAPI

Test if the hub is reachable.

```

cpp YRETCODE yTestHub( const string& url, int mstimeout, string& errmsg)
m    +(YRETCODE) TestHub : (NSString*) url
                                : (int) mstimeout
                                : (NSError**) errmsg
pas  function yTestHub( url: string,
                        mstimeout: integer,
                        var errmsg: string): integer
vb   function yTestHub( ByVal url As String,
                        ByVal mstimeout As Integer,
                        ByRef errmsg As String) As Integer
cs   int TestHub( string url, int mstimeout, ref string errmsg)
java int TestHub( String url, int mstimeout)
uwp  async Task<int> TestHub( string url, uint mstimeout)
py   def TestHub( url, mstimeout, errmsg=None)
php  function yTestHub( $url, $mstimeout, &$errmsg)
es   function TestHub( url, mstimeout)

```

This method do not register the hub, it only test if the hub is usable. The url parameter follow the same convention as the RegisterHub method. This method is useful to verify the authentication parameters for a hub. It is possible to force this method to return after mstimeout milliseconds.

Parameters :

- url** a string containing either "usb", "callback" or the root URL of the hub to monitor
- mstimeout** the number of millisecond available to test the connection.
- errmsg** a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure returns a negative error code.

YAPI.TriggerHubDiscovery() yTriggerHubDiscovery()

YAPI

Force a hub discovery, if a callback as been registered with yRegisterHubDiscoveryCallback it will be called for each net work hub that will respond to the discovery.

cpp	YRETCODE yTriggerHubDiscovery(string& errmsg)
m	+(YRETCODE) TriggerHubDiscovery : (NSError**) errmsg
pas	function yTriggerHubDiscovery(var errmsg: string): integer
vb	function yTriggerHubDiscovery(ByRef errmsg As String) As Integer
cs	int TriggerHubDiscovery(ref string errmsg)
java	int TriggerHubDiscovery()
uwp	async Task<int> TriggerHubDiscovery()
py	def TriggerHubDiscovery(errmsg=None)

Parameters :

errmsg a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds. On failure, throws an exception or returns a negative error code.

YAPI.UnregisterHub() yUnregisterHub()

YAPI

Setup the Yoctopuce library to no more use modules connected on a previously registered machine with RegisterHub.

js	function yUnregisterHub (url)
cpp	void yUnregisterHub (const string& url)
m	+(void) UnregisterHub :(NSString *) url
pas	procedure yUnregisterHub (url: string)
vb	procedure yUnregisterHub (ByVal url As String)
cs	void UnregisterHub (string url)
java	void UnregisterHub (String url)
uwp	async Task UnregisterHub (string url)
py	def UnregisterHub (url)
php	function yUnregisterHub (\$url)
es	function UnregisterHub (url)

Parameters :

url a string containing either "usb" or the

YAPI.UpdateDeviceList() yUpdateDeviceList()

YAPI

Triggers a (re)detection of connected Yoctopuce modules.

js	function yUpdateDeviceList (errmsg)
cpp	YRETCODE yUpdateDeviceList (string& errmsg)
m	+(YRETCODE) UpdateDeviceList :(NSError**) errmsg
pas	function yUpdateDeviceList (var errmsg : string): integer
vb	function yUpdateDeviceList (ByRef errmsg As String) As YRETCODE
cs	YRETCODE UpdateDeviceList (ref string errmsg)
java	int UpdateDeviceList ()
uwp	async Task<int> UpdateDeviceList ()
py	def UpdateDeviceList (errmsg =None)
php	function yUpdateDeviceList (&\$ errmsg)
es	function UpdateDeviceList (errmsg)

The library searches the machines or USB ports previously registered using `yRegisterHub()`, and invokes any user-defined callback function in case a change in the list of connected devices is detected.

This function can be called as frequently as desired to refresh the device list and to make the application aware of hot-plug events.

Parameters :

errmsg a string passed by reference to receive any error message.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

YAPI.UpdateDeviceList_async() yUpdateDeviceList_async()

YAPI

Triggers a (re)detection of connected Yoctopuce modules.

```
js function yUpdateDeviceList_async( callback, context)
```

The library searches the machines or USB ports previously registered using `yRegisterHub()`, and invokes any user-defined callback function in case a change in the list of connected devices is detected.

This function can be called as frequently as desired to refresh the device list and to make the application aware of hot-plug events.

This asynchronous version exists only in Javascript. It uses a callback instead of a return value in order to avoid blocking Firefox Javascript VM that does not implement context switching during blocking I/O calls.

Parameters :

callback callback function that is invoked when the result is known. The callback function receives three arguments: the caller-specific context object, the result code (`YAPI_SUCCESS` if the operation completes successfully) and the error message.

context caller-specific object that is passed as-is to the callback function

Returns :

nothing : the result is provided to the callback.

20.2. Module control interface

This interface is identical for all Yoctopuce USB modules. It can be used to control the module global parameters, and to enumerate the functions provided by each module.

In order to use the functions described here, you should include:

js	<code><script type='text/javascript' src='yocto_api.js'></script></code>
cpp	<code>#include "yocto_api.h"</code>
m	<code>#import "yocto_api.h"</code>
pas	<code>uses yocto_api;</code>
vb	<code>yocto_api.vb</code>
cs	<code>yocto_api.cs</code>
java	<code>import com.yoctopuce.YoctoAPI.YModule;</code>
uwp	<code>import com.yoctopuce.YoctoAPI.YModule;</code>
py	<code>from yocto_api import *</code>
php	<code>require_once('yocto_api.php');</code>
es	in HTML: <code><script src='../lib/yocto_api.js'></script></code> in node.js: <code>require('yoctolib-es2017/yocto_api.js');</code>

Global functions

yFindModule(func)

Allows you to find a module from its serial number or from its logical name.

yFindModuleInContext(yctx, func)

Retrieves a module for a given identifier in a YAPI context.

yFirstModule()

Starts the enumeration of modules currently accessible.

YModule methods

module→checkFirmware(path, onlynew)

Tests whether the byn file is valid for this module.

module→clearCache()

Invalidates the cache.

module→describe()

Returns a descriptive text that identifies the module.

module→download(pathname)

Downloads the specified built-in file and returns a binary buffer with its content.

module→functionBaseType(functionIndex)

Retrieves the base type of the *n*th function on the module.

module→functionCount()

Returns the number of functions (beside the "module" interface) available on the module.

module→functionId(functionIndex)

Retrieves the hardware identifier of the *n*th function on the module.

module→functionName(functionIndex)

Retrieves the logical name of the *n*th function on the module.

module→functionType(functionIndex)

Retrieves the type of the *n*th function on the module.

module→functionValue(functionIndex)

Retrieves the advertised value of the *n*th function on the module.

module→get_allSettings()

Returns all the settings and uploaded files of the module.
module→get_beacon() Returns the state of the localization beacon.
module→get_errorMessage() Returns the error message of the latest error with this module object.
module→get_errorType() Returns the numerical error code of the latest error with this module object.
module→get_firmwareRelease() Returns the version of the firmware embedded in the module.
module→get_functionIds(funType) Retrieve all hardware identifier that match the type passed in argument.
module→get_hardwareId() Returns the unique hardware identifier of the module.
module→get_icon2d() Returns the icon of the module.
module→get_lastLogs() Returns a string with last logs of the module.
module→get_logicalName() Returns the logical name of the module.
module→get_luminosity() Returns the luminosity of the module informative leds (from 0 to 100).
module→get_parentHub() Returns the serial number of the YoctoHub on which this module is connected.
module→get_persistentSettings() Returns the current state of persistent module settings.
module→get_productId() Returns the USB device identifier of the module.
module→get_productName() Returns the commercial name of the module, as set by the factory.
module→get_productRelease() Returns the hardware release version of the module.
module→get_rebootCountdown() Returns the remaining number of seconds before the module restarts, or zero when no reboot has been scheduled.
module→get_serialNumber() Returns the serial number of the module, as set by the factory.
module→get_subDevices() Returns a list of all the modules that are plugged into the current module.
module→get_upTime() Returns the number of milliseconds spent since the module was powered on.
module→get_url() Returns the URL used to access the module.
module→get_usbCurrent() Returns the current consumed by the module on the USB bus, in milli-amps.
module→get_userData() Returns the value of the userData attribute, as previously stored using method <code>set_userData</code> .

module→get_userVar()

Returns the value previously stored in this attribute.

module→hasFunction(funcId)

Tests if the device includes a specific function.

module→isOnline()

Checks if the module is currently reachable, without raising any error.

module→isOnline_async(callback, context)

Checks if the module is currently reachable, without raising any error.

module→load(msValidity)

Preloads the module cache with a specified validity duration.

module→load_async(msValidity, callback, context)

Preloads the module cache with a specified validity duration (asynchronous version).

module→log(text)

Adds a text message to the device logs.

module→nextModule()

Continues the module enumeration started using `yFirstModule()`.

module→reboot(secBeforeReboot)

Schedules a simple module reboot after the given number of seconds.

module→registerLogCallback(callback)

Registers a device log callback function.

module→revertFromFlash()

Reloads the settings stored in the nonvolatile memory, as when the module is powered on.

module→saveToFlash()

Saves current settings in the nonvolatile memory of the module.

module→set_allSettings(settings)

Restores all the settings of the device.

module→set_allSettingsAndFiles(settings)

Restores all the settings and uploaded files to the module.

module→set_beacon(newval)

Turns on or off the module localization beacon.

module→set_logicalName(newval)

Changes the logical name of the module.

module→set_luminosity(newval)

Changes the luminosity of the module informative leds.

module→set_userData(data)

Stores a user context provided as argument in the `userData` attribute of the function.

module→set_userVar(newval)

Stores a 32 bit value in the device RAM.

module→triggerFirmwareUpdate(secBeforeReboot)

Schedules a module reboot into special firmware update mode.

module→updateFirmware(path)

Prepares a firmware update of the module.

module→updateFirmwareEx(path, force)

Prepares a firmware update of the module.

module→wait_async(callback, context)

Waits for all pending asynchronous commands on the module to complete, and invoke the user-provided callback function.

YModule.FindModule() yFindModule()

YModule

Allows you to find a module from its serial number or from its logical name.

js	function yFindModule (func)
cpp	YModule* yFindModule (string func)
m	+(YModule*) FindModule : (NSString*) func
pas	function yFindModule (func : string): TYModule
vb	function yFindModule (ByVal func As String) As YModule
cs	YModule FindModule (string func)
java	YModule FindModule (String func)
uwp	YModule FindModule (string func)
py	def FindModule (func)
php	function yFindModule (\$func)
es	function FindModule (func)

This function does not require that the module is online at the time it is invoked. The returned object is nevertheless valid. Use the method `YModule.isOnline()` to test if the module is indeed online at a given time. In case of ambiguity when looking for a module by logical name, no error is notified: the first instance found is returned. The search is performed first by hardware name, then by logical name. If a call to this object's `is_online()` method returns `FALSE` although you are certain that the device is plugged, make sure that you did call `registerHub()` at application initialization time.

Parameters :

func a string containing either the serial number or the logical name of the desired module

Returns :

a `YModule` object allowing you to drive the module or get additional information on the module.

YModule.FindModuleInContext() yFindModuleInContext()

YModule

Retrieves a module for a given identifier in a YAPI context.

java	YModule FindModuleInContext(YAPIContext yctx , String func)
uwp	YModule FindModuleInContext(YAPIContext yctx , string func)
es	function FindModuleInContext(yctx , func)

The identifier can be specified using several formats:

- FunctionLogicalName
- ModuleSerialNumber.FunctionIdentifier
- ModuleSerialNumber.FunctionLogicalName
- ModuleLogicalName.FunctionIdentifier
- ModuleLogicalName.FunctionLogicalName

This function does not require that the module is online at the time it is invoked. The returned object is nevertheless valid. Use the method `YModule.isOnline()` to test if the module is indeed online at a given time. In case of ambiguity when looking for a module by logical name, no error is notified: the first instance found is returned. The search is performed first by hardware name, then by logical name.

Parameters :

yctx a YAPI context
func a string that uniquely characterizes the module

Returns :

a `YModule` object allowing you to drive the module.

YModule.FirstModule() yFirstModule()

YModule

Starts the enumeration of modules currently accessible.

js	function yFirstModule ()
cpp	YModule* yFirstModule ()
m	+(YModule*) FirstModule
pas	function yFirstModule (): TYModule
vb	function yFirstModule () As YModule
cs	YModule FirstModule ()
java	YModule FirstModule ()
uwp	YModule FirstModule ()
py	def FirstModule ()
php	function yFirstModule ()
es	function FirstModule ()

Use the method `YModule.nextModule()` to iterate on the next modules.

Returns :

a pointer to a `YModule` object, corresponding to the first module currently online, or a `null` pointer if there are none.

module→checkFirmware()**YModule**

Tests whether the byn file is valid for this module.

js	function checkFirmware (path , onlynew)
cpp	string checkFirmware (string path , bool onlynew)
m	-(NSString*) checkFirmware : (NSString*) path : (bool) onlynew
pas	function checkFirmware (path : string, onlynew : boolean): string
vb	function checkFirmware () As String
cs	string checkFirmware (string path , bool onlynew)
java	String checkFirmware (String path , boolean onlynew)
uwp	async Task<string> checkFirmware (string path , bool onlynew)
py	def checkFirmware (path , onlynew)
php	function checkFirmware (\$ path , \$ onlynew)
es	function checkFirmware (path , onlynew)
cmd	YModule target checkFirmware path onlynew

This method is useful to test if the module needs to be updated. It is possible to pass a directory as argument instead of a file. In this case, this method returns the path of the most recent appropriate .byn file. If the parameter `onlynew` is true, the function discards firmwares that are older or equal to the installed firmware.

Parameters :

- path** the path of a byn file or a directory that contains byn files
- onlynew** returns only files that are strictly newer

Returns :

the path of the byn file to use or a empty string if no byn files matches the requirement

On failure, throws an exception or returns a string that start with "error:".

module→clearCache()**YModule**

Invalidates the cache.

js	function clearCache ()
cpp	void clearCache ()
m	-(void) clearCache
pas	procedure clearCache ()
vb	procedure clearCache ()
cs	void clearCache ()
java	void clearCache ()
py	def clearCache ()
php	function clearCache ()
es	function clearCache ()

Invalidates the cache of the module attributes. Forces the next call to `get_xxx()` or `loadxxx()` to use values that come from the device.

module→describe()**YModule**

Returns a descriptive text that identifies the module.

js	function describe ()
cpp	string describe ()
m	-(NSString*) describe
pas	function describe (): string
vb	function describe () As String
cs	string describe ()
java	String describe ()
py	def describe ()
php	function describe ()
es	function describe ()

The text may include either the logical name or the serial number of the module.

Returns :

a string that describes the module

module→download()**YModule**

Downloads the specified built-in file and returns a binary buffer with its content.

js	function download (pathname)
cpp	string download (string pathname)
m	-(NSMutableData*) download : (NSString*) pathname
pas	function download (pathname : string): TByteArray
vb	function download () As Byte
cs	byte[] download (string pathname)
java	byte[] download (String pathname)
uwp	async Task<byte[]> download (string pathname)
py	def download (pathname)
php	function download (\$pathname)
es	function download (pathname)
cmd	YModule target download pathname

Parameters :

pathname name of the new file to load

Returns :

a binary buffer with the file content

On failure, throws an exception or returns YAPI_INVALID_STRING.

module→functionBaseType()**YModule**

Retrieves the base type of the *n*th function on the module.

js	function functionBaseType (functionIndex)
cpp	string functionBaseType (int functionIndex)
pas	function functionBaseType (functionIndex : integer): string
vb	function functionBaseType (ByVal functionIndex As Integer) As String
cs	string functionBaseType (int functionIndex)
java	String functionBaseType (int functionIndex)
py	def functionBaseType (functionIndex)
php	function functionBaseType (\$functionIndex)
es	function functionBaseType (functionIndex)

For instance, the base type of all measuring functions is "Sensor".

Parameters :

functionIndex the index of the function for which the information is desired, starting at 0 for the first function.

Returns :

a string corresponding to the base type of the function

On failure, throws an exception or returns an empty string.

module→functionCount()**YModule**

Returns the number of functions (beside the "module" interface) available on the module.

js	function functionCount ()
cpp	int functionCount ()
m	-(int) functionCount
pas	function functionCount (): integer
vb	function functionCount () As Integer
cs	int functionCount ()
java	int functionCount ()
py	def functionCount ()
php	function functionCount ()
es	function functionCount ()

Returns :

the number of functions on the module

On failure, throws an exception or returns a negative error code.

module→**functionId()****YModule**

Retrieves the hardware identifier of the *n*th function on the module.

js	function functionId (functionIndex)
cpp	string functionId (int functionIndex)
m	-(NSString*) functionId : (int) functionIndex
pas	function functionId (functionIndex : integer): string
vb	function functionId (ByVal functionIndex As Integer) As String
cs	string functionId (int functionIndex)
java	String functionId (int functionIndex)
py	def functionId (functionIndex)
php	function functionId (\$ functionIndex)
es	function functionId (functionIndex)

Parameters :

functionIndex the index of the function for which the information is desired, starting at 0 for the first function.

Returns :

a string corresponding to the unambiguous hardware identifier of the requested module function

On failure, throws an exception or returns an empty string.

module→**functionName()****YModule**

Retrieves the logical name of the n th function on the module.

js	function functionName (functionIndex)
cpp	string functionName (int functionIndex)
m	-(NSString*) functionName : (int) functionIndex
pas	function functionName (functionIndex : integer): string
vb	function functionName (ByVal functionIndex As Integer) As String
cs	string functionName (int functionIndex)
java	String functionName (int functionIndex)
py	def functionName (functionIndex)
php	function functionName (\$functionIndex)
es	function functionName (functionIndex)

Parameters :

functionIndex the index of the function for which the information is desired, starting at 0 for the first function.

Returns :

a string corresponding to the logical name of the requested module function

On failure, throws an exception or returns an empty string.

module→functionType()**YModule**

Retrieves the type of the *n*th function on the module.

js	function functionType (functionIndex)
cpp	string functionType (int functionIndex)
pas	function functionType (functionIndex : integer): string
vb	function functionType (ByVal functionIndex As Integer) As String
cs	string functionType (int functionIndex)
java	String functionType (int functionIndex)
py	def functionType (functionIndex)
php	function functionType (\$functionIndex)
es	function functionType (functionIndex)

Parameters :

functionIndex the index of the function for which the information is desired, starting at 0 for the first function.

Returns :

a string corresponding to the type of the function

On failure, throws an exception or returns an empty string.

module→**functionValue()****YModule**

Retrieves the advertised value of the *n*th function on the module.

js	function functionValue (functionIndex)
cpp	string functionValue (int functionIndex)
m	-(NSString*) functionValue : (int) functionIndex
pas	function functionValue (functionIndex : integer): string
vb	function functionValue (ByVal functionIndex As Integer) As String
cs	string functionValue (int functionIndex)
java	String functionValue (int functionIndex)
py	def functionValue (functionIndex)
php	function functionValue (\$functionIndex)
es	function functionValue (functionIndex)

Parameters :

functionIndex the index of the function for which the information is desired, starting at 0 for the first function.

Returns :

a short string (up to 6 characters) corresponding to the advertised value of the requested module function

On failure, throws an exception or returns an empty string.

module→get_allSettings()**YModule****module→allSettings()**

Returns all the settings and uploaded files of the module.

js	function get_allSettings ()
cpp	string get_allSettings ()
m	-(NSMutableData*) allSettings
pas	function get_allSettings (): TByteArray
vb	function get_allSettings () As Byte
cs	byte[] get_allSettings ()
java	byte[] get_allSettings ()
uwp	async Task<byte[]> get_allSettings ()
py	def get_allSettings ()
php	function get_allSettings ()
es	function get_allSettings ()
cmd	YModule target get_allSettings

Useful to backup all the logical names, calibrations parameters, and uploaded files of a device.

Returns :

a binary buffer with all the settings.

On failure, throws an exception or returns an binary object of size 0.

module→**get_beacon()****YModule****module**→**beacon()**

Returns the state of the localization beacon.

js	function get_beacon ()
cpp	Y_BEACON_enum get_beacon ()
m	-(Y_BEACON_enum) beacon
pas	function get_beacon (): Integer
vb	function get_beacon () As Integer
cs	int get_beacon ()
java	int get_beacon ()
uwp	async Task<int> get_beacon ()
py	def get_beacon ()
php	function get_beacon ()
es	function get_beacon ()
cmd	YModule target get_beacon

Returns :

either Y_BEACON_OFF or Y_BEACON_ON, according to the state of the localization beacon

On failure, throws an exception or returns Y_BEACON_INVALID.

module→**get_errorMessage()**
module→**errorMessage()**

YModule

Returns the error message of the latest error with this module object.

js	function get_errorMessage ()
cpp	string get_errorMessage ()
m	-(NSString*) errorMessage
pas	function get_errorMessage (): string
vb	function get_errorMessage () As String
cs	string get_errorMessage ()
java	String get_errorMessage ()
py	def get_errorMessage ()
php	function get_errorMessage ()
es	function get_errorMessage ()

This method is mostly useful when using the Yoctopuce library with exceptions disabled.

Returns :

a string corresponding to the latest error message that occurred while using this module object

module→**get_errorType()****YModule****module**→**errorType()**

Returns the numerical error code of the latest error with this module object.

js	function get_errorType ()
cpp	YRETCODE get_errorType ()
pas	function get_errorType (): YRETCODE
vb	function get_errorType () As YRETCODE
cs	YRETCODE get_errorType ()
java	int get_errorType ()
py	def get_errorType ()
php	function get_errorType ()
es	function get_errorType ()

This method is mostly useful when using the Yoctopuce library with exceptions disabled.

Returns :

a number corresponding to the code of the latest error that occurred while using this module object

module→**get_firmwareRelease()**
module→**firmwareRelease()**

YModule

Returns the version of the firmware embedded in the module.

js	function get_firmwareRelease ()
cpp	string get_firmwareRelease ()
m	-(NSString*) firmwareRelease
pas	function get_firmwareRelease (): string
vb	function get_firmwareRelease () As String
cs	string get_firmwareRelease ()
java	String get_firmwareRelease ()
uwp	async Task<string> get_firmwareRelease ()
py	def get_firmwareRelease ()
php	function get_firmwareRelease ()
es	function get_firmwareRelease ()
cmd	YModule target get_firmwareRelease

Returns :

a string corresponding to the version of the firmware embedded in the module

On failure, throws an exception or returns Y_FIRMWARERELEASE_INVALID.

module→get_functionIds()

module→functionIds()

YModule

Retrieve all hardware identifier that match the type passed in argument.

js	function get_functionIds (funType)
cpp	vector<string> get_functionIds (string funType)
m	-(NSMutableArray*) functionIds : (NSString*) funType
pas	function get_functionIds (funType : string): TStringArray
vb	function get_functionIds () As List
cs	List<string> get_functionIds (string funType)
java	ArrayList<String> get_functionIds (String funType)
uwp	async Task<List<string>> get_functionIds (string funType)
py	def get_functionIds (funType)
php	function get_functionIds (\$ funType)
es	function get_functionIds (funType)
cmd	YModule target get_functionIds funType

Parameters :

funType The type of function (Relay, LightSensor, Voltage,...)

Returns :

an array of strings.

module→**get_hardwareId()****YModule****module**→**hardwareId()**

Returns the unique hardware identifier of the module.

js	function get_hardwareId ()
cpp	string get_hardwareId ()
m	-(NSString*) hardwareId
vb	function get_hardwareId () As String
cs	string get_hardwareId ()
java	String get_hardwareId ()
py	def get_hardwareId ()
php	function get_hardwareId ()
es	function get_hardwareId ()

The unique hardware identifier is made of the device serial number followed by string ".module".

Returns :

a string that uniquely identifies the module

module→**get_icon2d()****YModule****module**→**icon2d()**

Returns the icon of the module.

js	function get_icon2d ()
cpp	string get_icon2d ()
m	-(NSData*) icon2d
pas	function get_icon2d (): TByteArray
vb	function get_icon2d () As Byte
cs	byte[] get_icon2d ()
java	byte[] get_icon2d ()
uwp	async Task<byte[]> get_icon2d ()
py	def get_icon2d ()
php	function get_icon2d ()
es	function get_icon2d ()
cmd	YModule target get_icon2d

The icon is a PNG image and does not exceeds 1536 bytes.

Returns :

a binary buffer with module icon, in png format. On failure, throws an exception or returns YAPI_INVALID_STRING.

module→get_lastLogs()**YModule****module→lastLogs()**

Returns a string with last logs of the module.

js	function get_lastLogs ()
cpp	string get_lastLogs ()
m	-(NSString*) lastLogs
pas	function get_lastLogs (): string
vb	function get_lastLogs () As String
cs	string get_lastLogs ()
java	String get_lastLogs ()
uwp	async Task<string> get_lastLogs ()
py	def get_lastLogs ()
php	function get_lastLogs ()
es	function get_lastLogs ()
cmd	YModule target get_lastLogs

This method return only logs that are still in the module.

Returns :

a string with last logs of the module. On failure, throws an exception or returns YAPI_INVALID_STRING.

module→get_logicalName()
module→logicalName()**YModule**

Returns the logical name of the module.

js	function get_logicalName ()
cpp	string get_logicalName ()
m	-(NSString*) logicalName
pas	function get_logicalName (): string
vb	function get_logicalName () As String
cs	string get_logicalName ()
java	String get_logicalName ()
uwp	async Task<string> get_logicalName ()
py	def get_logicalName ()
php	function get_logicalName ()
es	function get_logicalName ()
cmd	YModule target get_logicalName

Returns :

a string corresponding to the logical name of the module

On failure, throws an exception or returns Y_LOGICALNAME_INVALID.

module→get_luminosity()
module→luminosity()

YModule

Returns the luminosity of the module informative leds (from 0 to 100).

js	function get_luminosity ()
cpp	int get_luminosity ()
m	-(int) luminosity
pas	function get_luminosity (): LongInt
vb	function get_luminosity () As Integer
cs	int get_luminosity ()
java	int get_luminosity ()
uwp	async Task<int> get_luminosity ()
py	def get_luminosity ()
php	function get_luminosity ()
es	function get_luminosity ()
cmd	YModule target get_luminosity

Returns :

an integer corresponding to the luminosity of the module informative leds (from 0 to 100)

On failure, throws an exception or returns Y_LUMINOSITY_INVALID.

module→**get_parentHub()****YModule****module**→**parentHub()**

Returns the serial number of the YoctoHub on which this module is connected.

js	function get_parentHub ()
cpp	string get_parentHub ()
m	-(NSString*) parentHub
pas	function get_parentHub (): string
vb	function get_parentHub () As String
cs	string get_parentHub ()
java	String get_parentHub ()
py	def get_parentHub ()
php	function get_parentHub ()
cmd	YModule target get_parentHub

If the module is connected by USB, or if the module is the root YoctoHub, an empty string is returned.

Returns :

a string with the serial number of the YoctoHub or an empty string

module→get_persistentSettings()**YModule****module→persistentSettings()**

Returns the current state of persistent module settings.

js	function get_persistentSettings ()
cpp	Y_PERSISTENTSETTINGS_enum get_persistentSettings ()
m	-(Y_PERSISTENTSETTINGS_enum) persistentSettings
pas	function get_persistentSettings (): Integer
vb	function get_persistentSettings () As Integer
cs	int get_persistentSettings ()
java	int get_persistentSettings ()
uwp	async Task<int> get_persistentSettings ()
py	def get_persistentSettings ()
php	function get_persistentSettings ()
es	function get_persistentSettings ()
cmd	YModule target get_persistentSettings

Returns :

a value among Y_PERSISTENTSETTINGS_LOADED, Y_PERSISTENTSETTINGS_SAVED and Y_PERSISTENTSETTINGS_MODIFIED corresponding to the current state of persistent module settings

On failure, throws an exception or returns Y_PERSISTENTSETTINGS_INVALID.

module→**get_productId()****YModule****module**→**productId()**

Returns the USB device identifier of the module.

js	function get_productId ()
cpp	int get_productId ()
m	-(int) productId
pas	function get_productId (): LongInt
vb	function get_productId () As Integer
cs	int get_productId ()
java	int get_productId ()
uwp	async Task<int> get_productId ()
py	def get_productId ()
php	function get_productId ()
es	function get_productId ()
cmd	YModule target get_productId

Returns :

an integer corresponding to the USB device identifier of the module

On failure, throws an exception or returns Y_PRODUCTID_INVALID.

module→get_productName()**YModule****module→productName()**

Returns the commercial name of the module, as set by the factory.

js	function get_productName ()
cpp	string get_productName ()
m	-(NSString*) productName
pas	function get_productName (): string
vb	function get_productName () As String
cs	string get_productName ()
java	String get_productName ()
uwp	async Task<string> get_productName ()
py	def get_productName ()
php	function get_productName ()
es	function get_productName ()
cmd	YModule target get_productName

Returns :

a string corresponding to the commercial name of the module, as set by the factory

On failure, throws an exception or returns Y_PRODUCTNAME_INVALID.

module→**get_productRelease()****YModule****module**→**productRelease()**

Returns the hardware release version of the module.

js	function get_productRelease ()
cpp	int get_productRelease ()
m	-(int) productRelease
pas	function get_productRelease (): LongInt
vb	function get_productRelease () As Integer
cs	int get_productRelease ()
java	int get_productRelease ()
uwp	async Task<int> get_productRelease ()
py	def get_productRelease ()
php	function get_productRelease ()
es	function get_productRelease ()
cmd	YModule target get_productRelease

Returns :

an integer corresponding to the hardware release version of the module

On failure, throws an exception or returns Y_PRODUCTRELEASE_INVALID.

module→get_rebootCountdown()**YModule****module→rebootCountdown()**

Returns the remaining number of seconds before the module restarts, or zero when no reboot has been scheduled.

js	function get_rebootCountdown ()
cpp	int get_rebootCountdown ()
m	-(int) rebootCountdown
pas	function get_rebootCountdown (): LongInt
vb	function get_rebootCountdown () As Integer
cs	int get_rebootCountdown ()
java	int get_rebootCountdown ()
uwp	async Task<int> get_rebootCountdown ()
py	def get_rebootCountdown ()
php	function get_rebootCountdown ()
es	function get_rebootCountdown ()
cmd	YModule target get_rebootCountdown

Returns :

an integer corresponding to the remaining number of seconds before the module restarts, or zero when no reboot has been scheduled

On failure, throws an exception or returns Y_REBOOTCOUNTDOWN_INVALID.

module→**get_serialNumber()****YModule****module**→**serialNumber()**

Returns the serial number of the module, as set by the factory.

js	function get_serialNumber ()
cpp	string get_serialNumber ()
m	-(NSString*) serialNumber
pas	function get_serialNumber (): string
vb	function get_serialNumber () As String
cs	string get_serialNumber ()
java	String get_serialNumber ()
uwp	async Task<string> get_serialNumber ()
py	def get_serialNumber ()
php	function get_serialNumber ()
es	function get_serialNumber ()
cmd	YModule target get_serialNumber

Returns :

a string corresponding to the serial number of the module, as set by the factory

On failure, throws an exception or returns Y_SERIALNUMBER_INVALID.

module→get_subDevices()**YModule****module→subDevices()**

Returns a list of all the modules that are plugged into the current module.

js	function get_subDevices ()
cpp	vector<string> get_subDevices ()
m	-(NSMutableArray*) subDevices
pas	function get_subDevices (): TStringArray
vb	function get_subDevices () As List
cs	List<string> get_subDevices ()
java	ArrayList<String> get_subDevices ()
py	def get_subDevices ()
php	function get_subDevices ()
cmd	YModule target get_subDevices

This method only makes sense when called for a YoctoHub/VirtualHub. Otherwise, an empty array will be returned.

Returns :

an array of strings containing the sub modules.

module→**get_upTime()****YModule****module**→**upTime()**

Returns the number of milliseconds spent since the module was powered on.

js	function get_upTime ()
cpp	s64 get_upTime ()
m	-(s64) upTime
pas	function get_upTime (): int64
vb	function get_upTime () As Long
cs	long get_upTime ()
java	long get_upTime ()
uwp	async Task<long> get_upTime ()
py	def get_upTime ()
php	function get_upTime ()
es	function get_upTime ()
cmd	YModule target get_upTime

Returns :

an integer corresponding to the number of milliseconds spent since the module was powered on

On failure, throws an exception or returns Y_UPTIME_INVALID.

module→get_url()**YModule****module→url()**

Returns the URL used to access the module.

js	function get_url ()
cpp	string get_url ()
m	-(NSString*) url
pas	function get_url (): string
vb	function get_url () As String
cs	string get_url ()
java	String get_url ()
py	def get_url ()
php	function get_url ()
cmd	YModule target get_url

If the module is connected by USB, the string 'usb' is returned.

Returns :

a string with the URL of the module.

module→**get_usbCurrent()****YModule****module**→**usbCurrent()**

Returns the current consumed by the module on the USB bus, in milli-amps.

js	function get_usbCurrent ()
cpp	int get_usbCurrent ()
m	-(int) usbCurrent
pas	function get_usbCurrent (): LongInt
vb	function get_usbCurrent () As Integer
cs	int get_usbCurrent ()
java	int get_usbCurrent ()
uwp	async Task<int> get_usbCurrent ()
py	def get_usbCurrent ()
php	function get_usbCurrent ()
es	function get_usbCurrent ()
cmd	YModule target get_usbCurrent

Returns :

an integer corresponding to the current consumed by the module on the USB bus, in milli-amps

On failure, throws an exception or returns Y_USBCURRENT_INVALID.

module→**get_userData()****YModule****module**→**userData()**

Returns the value of the userData attribute, as previously stored using method set_userData.

js	function get_userData ()
cpp	void * get_userData ()
m	-(id) userData
pas	function get_userData (): Tobject
vb	function get_userData () As Object
cs	object get_userData ()
java	Object get_userData ()
py	def get_userData ()
php	function get_userData ()
es	function get_userData ()

This attribute is never touched directly by the API, and is at disposal of the caller to store a context.

Returns :

the object stored previously by the caller.

module→**get_userVar()****YModule****module**→**userVar()**

Returns the value previously stored in this attribute.

js	function get_userVar ()
cpp	int get_userVar ()
m	-(int) userVar
pas	function get_userVar (): LongInt
vb	function get_userVar () As Integer
cs	int get_userVar ()
java	int get_userVar ()
uwp	async Task<int> get_userVar ()
py	def get_userVar ()
php	function get_userVar ()
es	function get_userVar ()
cmd	YModule target get_userVar

On startup and after a device reboot, the value is always reset to zero.

Returns :

an integer corresponding to the value previously stored in this attribute

On failure, throws an exception or returns Y_USERVAR_INVALID.

module→hasFunction()**YModule**

Tests if the device includes a specific function.

js	function hasFunction (funcId)
cpp	bool hasFunction (string funcId)
m	-(bool) hasFunction : (NSString*) funcId
pas	function hasFunction (funcId : string): boolean
vb	function hasFunction () As Boolean
cs	bool hasFunction (string funcId)
java	boolean hasFunction (String funcId)
uwp	async Task<bool> hasFunction (string funcId)
py	def hasFunction (funcId)
php	function hasFunction (\$funcId)
es	function hasFunction (funcId)
cmd	YModule target hasFunction funcId

This method takes a function identifier and returns a boolean.

Parameters :

funcId the requested function identifier

Returns :

true if the device has the function identifier

module→isOnline()**YModule**

Checks if the module is currently reachable, without raising any error.

js	function isOnline ()
cpp	bool isOnline ()
m	-(BOOL) isOnline
pas	function isOnline (): boolean
vb	function isOnline () As Boolean
cs	bool isOnline ()
java	boolean isOnline ()
py	def isOnline ()
php	function isOnline ()
es	function isOnline ()

If there are valid cached values for the module, that have not yet expired, the device is considered reachable. No exception is raised if there is an error while trying to contact the requested module.

Returns :

`true` if the module can be reached, and `false` otherwise

module→isOnline_async()**YModule**

Checks if the module is currently reachable, without raising any error.

```
js function isOnline_async( callback, context)
```

If there are valid cached values for the module, that have not yet expired, the device is considered reachable. No exception is raised if there is an error while trying to contact the requested module.

This asynchronous version exists only in Javascript. It uses a callback instead of a return value in order to avoid blocking Firefox Javascript VM that does not implement context switching during blocking I/O calls.

Parameters :

callback callback function that is invoked when the result is known. The callback function receives three arguments: the caller-specific context object, the receiving module object and the boolean result

context caller-specific object that is passed as-is to the callback function

Returns :

nothing : the result is provided to the callback.

module→load()**YModule**

Preloads the module cache with a specified validity duration.

js	function load (msValidity)
cpp	YRETCODE load (int msValidity)
m	-(YRETCODE) load : (int) msValidity
pas	function load (msValidity : integer): YRETCODE
vb	function load (ByVal msValidity As Integer) As YRETCODE
cs	YRETCODE load (ulong msValidity)
java	int load (long msValidity)
py	def load (msValidity)
php	function load (\$ msValidity)
es	function load (msValidity)

By default, whenever accessing a device, all module attributes are kept in cache for the standard duration (5 ms). This method can be used to temporarily mark the cache as valid for a longer period, in order to reduce network traffic for instance.

Parameters :

msValidity an integer corresponding to the validity attributed to the loaded module parameters, in milliseconds

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→load_async()**YModule**

Preloads the module cache with a specified validity duration (asynchronous version).

```
js function load_async( msValidity, callback, context)
```

By default, whenever accessing a device, all module attributes are kept in cache for the standard duration (5 ms). This method can be used to temporarily mark the cache as valid for a longer period, in order to reduce network traffic for instance.

This asynchronous version exists only in Javascript. It uses a callback instead of a return value in order to avoid blocking Firefox javascript VM that does not implement context switching during blocking I/O calls. See the documentation section on asynchronous Javascript calls for more details.

Parameters :

- msValidity** an integer corresponding to the validity of the loaded module parameters, in milliseconds
- callback** callback function that is invoked when the result is known. The callback function receives three arguments: the caller-specific context object, the receiving module object and the error code (or YAPI_SUCCESS)
- context** caller-specific object that is passed as-is to the callback function

Returns :

nothing : the result is provided to the callback.

module→log()**YModule**

Adds a text message to the device logs.

js	function log (text)
cpp	int log (string text)
m	-(int) log : (NSString*) text
pas	function log (text : string): LongInt
vb	function log () As Integer
cs	int log (string text)
java	int log (String text)
uwp	async Task<int> log (string text)
py	def log (text)
php	function log (\$text)
es	function log (text)
cmd	YModule target log text

This function is useful in particular to trace the execution of HTTP callbacks. If a newline is desired after the message, it must be included in the string.

Parameters :

text the string to append to the logs.

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

module→nextModule()**YModule**

Continues the module enumeration started using `yFirstModule()`.

js	function nextModule ()
cpp	YModule * nextModule ()
m	-(YModule*) nextModule
pas	function nextModule (): TModule
vb	function nextModule () As YModule
cs	YModule nextModule ()
java	YModule nextModule ()
uwp	YModule nextModule ()
py	def nextModule ()
php	function nextModule ()
es	function nextModule ()

Returns :

a pointer to a `YModule` object, corresponding to the next module found, or a `null` pointer if there are no more modules to enumerate.

module→reboot()**YModule**

Schedules a simple module reboot after the given number of seconds.

js	function reboot (secBeforeReboot)
cpp	int reboot (int secBeforeReboot)
m	-(int) reboot : (int) secBeforeReboot
pas	function reboot (secBeforeReboot : LongInt): LongInt
vb	function reboot () As Integer
cs	int reboot (int secBeforeReboot)
java	int reboot (int secBeforeReboot)
uwp	async Task<int> reboot (int secBeforeReboot)
py	def reboot (secBeforeReboot)
php	function reboot (\$secBeforeReboot)
es	function reboot (secBeforeReboot)
cmd	YModule target reboot secBeforeReboot

Parameters :

secBeforeReboot number of seconds before rebooting

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→registerLogCallback()**YModule**

Registers a device log callback function.

cpp	void registerLogCallback (YModuleLogCallback callback)
m	-(void) registerLogCallback : (YModuleLogCallback) callback
vb	function registerLogCallback (ByVal callback As YModuleLogCallback) As Integer
cs	int registerLogCallback (LogCallback callback)
java	void registerLogCallback (LogCallback callback)
py	def registerLogCallback (callback)

This callback will be called each time that a module sends a new log message. Mostly useful to debug a Yoctopuce module.

Parameters :

callback the callback function to call, or a null pointer. The callback function should take two arguments: the module object that emitted the log message, and the character string containing the log.

module→revertFromFlash()**YModule**

Reloads the settings stored in the nonvolatile memory, as when the module is powered on.

js	function revertFromFlash ()
cpp	int revertFromFlash ()
m	-(int) revertFromFlash
pas	function revertFromFlash (): LongInt
vb	function revertFromFlash () As Integer
cs	int revertFromFlash ()
java	int revertFromFlash ()
uwp	async Task<int> revertFromFlash ()
py	def revertFromFlash ()
php	function revertFromFlash ()
es	function revertFromFlash ()
cmd	YModule target revertFromFlash

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→saveToFlash()**YModule**

Saves current settings in the nonvolatile memory of the module.

js	function saveToFlash ()
cpp	int saveToFlash ()
m	-(int) saveToFlash
pas	function saveToFlash (): LongInt
vb	function saveToFlash () As Integer
cs	int saveToFlash ()
java	int saveToFlash ()
uwp	async Task<int> saveToFlash ()
py	def saveToFlash ()
php	function saveToFlash ()
es	function saveToFlash ()
cmd	YModule target saveToFlash

Warning: the number of allowed save operations during a module life is limited (about 100000 cycles). Do not call this function within a loop.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→**set_allSettings()****YModule****module**→**setAllSettings()**

Restores all the settings of the device.

js	function set_allSettings (settings)
cpp	int set_allSettings (string settings)
m	-(int) setAllSettings : (NSData*) settings
pas	function set_allSettings (settings : TByteArray): LongInt
vb	procedure set_allSettings ()
cs	int set_allSettings ()
java	int set_allSettings (byte[] settings)
uwp	async Task<int> set_allSettings ()
py	def set_allSettings (settings)
php	function set_allSettings (\$settings)
es	function set_allSettings (settings)
cmd	YModule target set_allSettings settings

Useful to restore all the logical names and calibrations parameters of a module from a backup. Remember to call the `saveToFlash()` method of the module if the modifications must be kept.

Parameters :

settings a binary buffer with all the settings.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→set_allSettingsAndFiles()**YModule****module→setAllSettingsAndFiles()**

Restores all the settings and uploaded files to the module.

js	function set_allSettingsAndFiles (settings)
cpp	int set_allSettingsAndFiles (string settings)
m	-(int) setAllSettingsAndFiles : (NSData*) settings
pas	function set_allSettingsAndFiles (settings : TByteArray): LongInt
vb	procedure set_allSettingsAndFiles ()
cs	int set_allSettingsAndFiles ()
java	int set_allSettingsAndFiles (byte[] settings)
uwp	async Task<int> set_allSettingsAndFiles ()
py	def set_allSettingsAndFiles (settings)
php	function set_allSettingsAndFiles (\$ settings)
es	function set_allSettingsAndFiles (settings)
cmd	YModule target set_allSettingsAndFiles settings

This method is useful to restore all the logical names and calibrations parameters, uploaded files etc. of a device from a backup. Remember to call the `saveToFlash()` method of the module if the modifications must be kept.

Parameters :

settings a binary buffer with all the settings.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→**set_beacon()****YModule****module**→**setBeacon()**

Turns on or off the module localization beacon.

js	function set_beacon (newval)
cpp	int set_beacon (Y_BEACON_enum newval)
m	-(int) setBeacon : (Y_BEACON_enum) newval
pas	function set_beacon (newval : Integer): integer
vb	function set_beacon (ByVal newval As Integer) As Integer
cs	int set_beacon (int newval)
java	int set_beacon (int newval)
uwp	async Task<int> set_beacon (int newval)
py	def set_beacon (newval)
php	function set_beacon (\$newval)
es	function set_beacon (newval)
cmd	YModule target set_beacon newval

Parameters :

newval either Y_BEACON_OFF or Y_BEACON_ON

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

module→**set_logicalName()****YModule****module**→**setLogicalName()**

Changes the logical name of the module.

js	function set_logicalName (newval)
cpp	int set_logicalName (const string& newval)
m	-(int) setLogicalName : (NSString*) newval
pas	function set_logicalName (newval : string): integer
vb	function set_logicalName (ByVal newval As String) As Integer
cs	int set_logicalName (string newval)
java	int set_logicalName (String newval)
uwp	async Task<int> set_logicalName (string newval)
py	def set_logicalName (newval)
php	function set_logicalName (\$ newval)
es	function set_logicalName (newval)
cmd	YModule target set_logicalName newval

You can use `yCheckLogicalName( )` prior to this call to make sure that your parameter is valid. Remember to call the `saveToFlash( )` method of the module if the modification must be kept.

Parameters :

newval a string corresponding to the logical name of the module

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

module→**set_luminosity()****YModule****module**→**setLuminosity()**

Changes the luminosity of the module informative leds.

js	function set_luminosity (newval)
cpp	int set_luminosity (int newval)
m	-(int) setLuminosity : (int) newval
pas	function set_luminosity (newval : LongInt): integer
vb	function set_luminosity (ByVal newval As Integer) As Integer
cs	int set_luminosity (int newval)
java	int set_luminosity (int newval)
uwp	async Task<int> set_luminosity (int newval)
py	def set_luminosity (newval)
php	function set_luminosity (\$ newval)
es	function set_luminosity (newval)
cmd	YModule target set_luminosity newval

The parameter is a value between 0 and 100. Remember to call the `saveToFlash()` method of the module if the modification must be kept.

Parameters :

newval an integer corresponding to the luminosity of the module informative leds

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

module→**set_userData()****YModule****module**→**setUserData()**

Stores a user context provided as argument in the userData attribute of the function.

js	function set_userData (data)
cpp	void set_userData (void* data)
m	-(void) setUserData : (id) data
pas	procedure set_userData (data : Tobject)
vb	procedure set_userData (ByVal data As Object)
cs	void set_userData (object data)
java	void set_userData (Object data)
py	def set_userData (data)
php	function set_userData (\$ data)
es	function set_userData (data)

This attribute is never touched by the API, and is at disposal of the caller to store a context.

Parameters :

data any kind of object to be stored

module→**set_userVar()****YModule****module**→**setUserVar()**

Stores a 32 bit value in the device RAM.

js	function set_userVar (newval)
cpp	int set_userVar (int newval)
m	-(int) setUserVar : (int) newval
pas	function set_userVar (newval : LongInt): integer
vb	function set_userVar (ByVal newval As Integer) As Integer
cs	int set_userVar (int newval)
java	int set_userVar (int newval)
uwp	async Task<int> set_userVar (int newval)
py	def set_userVar (newval)
php	function set_userVar (\$newval)
es	function set_userVar (newval)
cmd	YModule target set_userVar newval

This attribute is at programmer disposal, should he need to store a state variable. On startup and after a device reboot, the value is always reset to zero.

Parameters :

newval an integer

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

module→triggerFirmwareUpdate()**YModule**

Schedules a module reboot into special firmware update mode.

js	function triggerFirmwareUpdate (secBeforeReboot)
cpp	int triggerFirmwareUpdate (int secBeforeReboot)
m	-(int) triggerFirmwareUpdate : (int) secBeforeReboot
pas	function triggerFirmwareUpdate (secBeforeReboot : LongInt): LongInt
vb	function triggerFirmwareUpdate () As Integer
cs	int triggerFirmwareUpdate (int secBeforeReboot)
java	int triggerFirmwareUpdate (int secBeforeReboot)
uwp	async Task<int> triggerFirmwareUpdate (int secBeforeReboot)
py	def triggerFirmwareUpdate (secBeforeReboot)
php	function triggerFirmwareUpdate (\$secBeforeReboot)
es	function triggerFirmwareUpdate (secBeforeReboot)
cmd	YModule target triggerFirmwareUpdate secBeforeReboot

Parameters :

secBeforeReboot number of seconds before rebooting

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

module→updateFirmware()**YModule**

Prepares a firmware update of the module.

js	function updateFirmware (path)
cpp	YFirmwareUpdate updateFirmware (string path)
m	-(YFirmwareUpdate*) updateFirmware : (NSString*) path
pas	function updateFirmware (path : string): TYFirmwareUpdate
vb	function updateFirmware () As YFirmwareUpdate
cs	YFirmwareUpdate updateFirmware (string path)
java	YFirmwareUpdate updateFirmware (String path)
uwp	async Task<YFirmwareUpdate> updateFirmware (string path)
py	def updateFirmware (path)
php	function updateFirmware (\$path)
es	function updateFirmware (path)
cmd	YModule target updateFirmware path

This method returns a YFirmwareUpdate object which handles the firmware update process.

Parameters :

path the path of the .byn file to use.

Returns :

a YFirmwareUpdate object or NULL on error.

module→updateFirmwareEx()**YModule**

Prepares a firmware update of the module.

js	function updateFirmwareEx (path , force)
cpp	YFirmwareUpdate updateFirmwareEx (string path , bool force)
m	-(YFirmwareUpdate*) updateFirmwareEx : (NSString*) path : (bool) force
pas	function updateFirmwareEx (path : string, force : boolean): TYFirmwareUpdate
vb	function updateFirmwareEx () As YFirmwareUpdate
cs	YFirmwareUpdate updateFirmwareEx (string path , bool force)
java	YFirmwareUpdate updateFirmwareEx (String path , boolean force)
uwp	async Task<YFirmwareUpdate> updateFirmwareEx (string path , bool force)
py	def updateFirmwareEx (path , force)
php	function updateFirmwareEx (\$path , \$force)
es	function updateFirmwareEx (path , force)
cmd	YModule target updateFirmwareEx path force

This method returns a YFirmwareUpdate object which handles the firmware update process.

Parameters :

path the path of the .byn file to use.

force true to force the firmware update even if some prerequisites appear not to be met

Returns :

a YFirmwareUpdate object or NULL on error.

module→**wait_async()****YModule**

Waits for all pending asynchronous commands on the module to complete, and invoke the user-provided callback function.

```
js function wait_async( callback, context)
```

```
es function wait_async( callback, context)
```

The callback function can therefore freely issue synchronous or asynchronous commands, without risking to block the Javascript VM.

Parameters :

callback callback function that is invoked when all pending commands on the module are completed. The callback function receives two arguments: the caller-specific context object and the receiving function object.

context caller-specific object that is passed as-is to the callback function

Returns :

nothing.

20.3. Relay function interface

The Yoctopuce application programming interface allows you to switch the relay state. This change is not persistent: the relay will automatically return to its idle position whenever power is lost or if the module is restarted. The library can also generate automatically short pulses of determined duration. On devices with two output for each relay (double throw), the two outputs are named A and B, with output A corresponding to the idle position (at power off) and the output B corresponding to the active state. If you prefer the alternate default state, simply switch your cables on the board.

In order to use the functions described here, you should include:

js	<script type='text/javascript' src='yocto_relay.js'></script>
cpp	#include "yocto_relay.h"
m	#import "yocto_relay.h"
pas	uses yocto_relay;
vb	yocto_relay.vb
cs	yocto_relay.cs
java	import com.yoctopuce.YoctoAPI.YRelay;
uwp	import com.yoctopuce.YoctoAPI.YRelay;
py	from yocto_relay import *
php	require_once('yocto_relay.php');
es	in HTML: <script src="../../lib/yocto_relay.js"></script> in node.js: require('yoctolib-es2017/yocto_relay.js');

Global functions

yFindRelay(func)

Retrieves a relay for a given identifier.

yFindRelayInContext(yctx, func)

Retrieves a relay for a given identifier in a YAPI context.

yFirstRelay()

Starts the enumeration of relays currently accessible.

yFirstRelayInContext(yctx)

Starts the enumeration of relays currently accessible.

YRelay methods

relay→clearCache()

Invalidates the cache.

relay→delayedPulse(ms_delay, ms_duration)

Schedules a pulse.

relay→describe()

Returns a short text that describes unambiguously the instance of the relay in the form TYPE(NAME)=SERIAL.FUNCTIONID.

relay→get_advertisedValue()

Returns the current value of the relay (no more than 6 characters).

relay→get_countdown()

Returns the number of milliseconds remaining before a pulse (delayedPulse() call) When there is no scheduled pulse, returns zero.

relay→get_errorMessage()

Returns the error message of the latest error with the relay.

relay→get_errorType()

Returns the numerical error code of the latest error with the relay.

relay→get_friendlyName()

Returns a global identifier of the relay in the format `MODULE_NAME . FUNCTION_NAME`.

relay→get_functionDescriptor()

Returns a unique identifier of type `YFUN_DESCR` corresponding to the function.

relay→get_functionId()

Returns the hardware identifier of the relay, without reference to the module.

relay→get_hardwareId()

Returns the unique hardware identifier of the relay in the form `SERIAL . FUNCTIONID`.

relay→get_logicalName()

Returns the logical name of the relay.

relay→get_maxTimeOnStateA()

Retourne the maximum time (ms) allowed for `$THEFUNCTIONS$` to stay in state A before automatically switching back in to B state.

relay→get_maxTimeOnStateB()

Retourne the maximum time (ms) allowed for `$THEFUNCTIONS$` to stay in state B before automatically switching back in to A state.

relay→get_module()

Gets the `YModule` object for the device on which the function is located.

relay→get_module_async(callback, context)

Gets the `YModule` object for the device on which the function is located (asynchronous version).

relay→get_output()

Returns the output state of the relays, when used as a simple switch (single throw).

relay→get_pulseTimer()

Returns the number of milliseconds remaining before the relays is returned to idle position (state A), during a measured pulse generation.

relay→get_state()

Returns the state of the relays (A for the idle position, B for the active position).

relay→get_stateAtPowerOn()

Returns the state of the relays at device startup (A for the idle position, B for the active position, `UNCHANGED` for no change).

relay→get_userData()

Returns the value of the `userData` attribute, as previously stored using method `set_userData`.

relay→isOnline()

Checks if the relay is currently reachable, without raising any error.

relay→isOnline_async(callback, context)

Checks if the relay is currently reachable, without raising any error (asynchronous version).

relay→load(msValidity)

Preloads the relay cache with a specified validity duration.

relay→loadAttribute(attrName)

Returns the current value of a single function attribute, as a text string, as quickly as possible but without using the cached value.

relay→load_async(msValidity, callback, context)

Preloads the relay cache with a specified validity duration (asynchronous version).

relay→muteValueCallbacks()

Disables the propagation of every new advertised value to the parent hub.

relay→nextRelay()

Continues the enumeration of relays started using `yFirstRelay()`.

relay→pulse(*ms_duration*)

Sets the relay to output B (active) for a specified duration, then brings it automatically back to output A (idle state).

relay→registerValueCallback(*callback*)

Registers the callback function that is invoked on every change of advertised value.

relay→set_logicalName(*newval*)

Changes the logical name of the relay.

relay→set_maxTimeOnStateA(*newval*)

Sets the maximum time (ms) allowed for \$THEFUNCTIONS\$ to stay in state A before automatically switching back in to B state.

relay→set_maxTimeOnStateB(*newval*)

Sets the maximum time (ms) allowed for \$THEFUNCTIONS\$ to stay in state B before automatically switching back in to A state.

relay→set_output(*newval*)

Changes the output state of the relays, when used as a simple switch (single throw).

relay→set_state(*newval*)

Changes the state of the relays (A for the idle position, B for the active position).

relay→set_stateAtPowerOn(*newval*)

Preset the state of the relays at device startup (A for the idle position, B for the active position, UNCHANGED for no modification).

relay→set_userData(*data*)

Stores a user context provided as argument in the `userData` attribute of the function.

relay→unmuteValueCallbacks()

Re-enables the propagation of every new advertised value to the parent hub.

relay→wait_async(*callback*, *context*)

Waits for all pending asynchronous commands on the module to complete, and invoke the user-provided callback function.

YRelay.FindRelay() yFindRelay()

YRelay

Retrieves a relay for a given identifier.

js	function yFindRelay (func)
cpp	YRelay* yFindRelay (string func)
m	+(YRelay*) FindRelay : (NSString*) func
pas	function yFindRelay (func : string): TYRelay
vb	function yFindRelay (ByVal func As String) As YRelay
cs	YRelay FindRelay (string func)
java	YRelay FindRelay (String func)
uwp	YRelay FindRelay (string func)
py	def FindRelay (func)
php	function yFindRelay (\$func)
es	function FindRelay (func)

The identifier can be specified using several formats:

- FunctionLogicalName
- ModuleSerialNumber.FunctionIdentifier
- ModuleSerialNumber.FunctionLogicalName
- ModuleLogicalName.FunctionIdentifier
- ModuleLogicalName.FunctionLogicalName

This function does not require that the relay is online at the time it is invoked. The returned object is nevertheless valid. Use the method `YRelay.isOnline()` to test if the relay is indeed online at a given time. In case of ambiguity when looking for a relay by logical name, no error is notified: the first instance found is returned. The search is performed first by hardware name, then by logical name. If a call to this object's `is_online()` method returns `FALSE` although you are certain that the matching device is plugged, make sure that you did call `registerHub()` at application initialization time.

Parameters :

func a string that uniquely characterizes the relay

Returns :

a `YRelay` object allowing you to drive the relay.

YRelay.FindRelayInContext() yFindRelayInContext()

YRelay

Retrieves a relay for a given identifier in a YAPI context.

```

java YRelay FindRelayInContext( YAPIContext yctx, String func)
uwp YRelay FindRelayInContext( YAPIContext yctx, string func)
es function FindRelayInContext( yctx, func)

```

The identifier can be specified using several formats:

- FunctionLogicalName
- ModuleSerialNumber.FunctionIdentifier
- ModuleSerialNumber.FunctionLogicalName
- ModuleLogicalName.FunctionIdentifier
- ModuleLogicalName.FunctionLogicalName

This function does not require that the relay is online at the time it is invoked. The returned object is nevertheless valid. Use the method `YRelay.isOnline()` to test if the relay is indeed online at a given time. In case of ambiguity when looking for a relay by logical name, no error is notified: the first instance found is returned. The search is performed first by hardware name, then by logical name.

Parameters :

yctx a YAPI context
func a string that uniquely characterizes the relay

Returns :

a `YRelay` object allowing you to drive the relay.

YRelay.FirstRelay() yFirstRelay()

YRelay

Starts the enumeration of relays currently accessible.

js	function yFirstRelay ()
cpp	YRelay* yFirstRelay ()
m	+(YRelay*) FirstRelay
pas	function yFirstRelay (): TYRelay
vb	function yFirstRelay () As YRelay
cs	YRelay FirstRelay ()
java	YRelay FirstRelay ()
uwp	YRelay FirstRelay ()
py	def FirstRelay ()
php	function yFirstRelay ()
es	function FirstRelay ()

Use the method `YRelay.nextRelay()` to iterate on next relays.

Returns :

a pointer to a `YRelay` object, corresponding to the first relay currently online, or a `null` pointer if there are none.

YRelay.FirstRelayInContext() yFirstRelayInContext()

YRelay

Starts the enumeration of relays currently accessible.

```
java YRelay FirstRelayInContext( YAPIContext yctx)
uwp YRelay FirstRelayInContext( YAPIContext yctx)
es function FirstRelayInContext( yctx)
```

Use the method `YRelay.nextRelay()` to iterate on next relays.

Parameters :

yctx a YAPI context.

Returns :

a pointer to a `YRelay` object, corresponding to the first relay currently online, or a `null` pointer if there are none.

relay→clearCache()**YRelay**

Invalidates the cache.

js	function clearCache ()
cpp	void clearCache ()
m	-(void) clearCache
pas	procedure clearCache ()
vb	procedure clearCache ()
cs	void clearCache ()
java	void clearCache ()
py	def clearCache ()
php	function clearCache ()
es	function clearCache ()

Invalidates the cache of the relay attributes. Forces the next call to `get_xxx()` or `loadxxx()` to use values that come from the device.

relay→describe()**YRelay**

Returns a short text that describes unambiguously the instance of the relay in the form `TYPE(NAME)=SERIAL.FUNCTIONID`.

js	function describe ()
cpp	string describe ()
m	-(NSString*) describe
pas	function describe (): string
vb	function describe () As String
cs	string describe ()
java	String describe ()
py	def describe ()
php	function describe ()
es	function describe ()

More precisely, TYPE is the type of the function, NAME it the name used for the first access to the function, SERIAL is the serial number of the module if the module is connected or "unresolved", and FUNCTIONID is the hardware identifier of the function if the module is connected. For example, this method returns `Relay(MyCustomName.relay1)=RELAYL01-123456.relay1` if the module is already connected or `Relay(BadCustomName.relay1)=unresolved` if the module has not yet been connected. This method does not trigger any USB or TCP transaction and can therefore be used in a debugger.

Returns :

a string that describes the relay (ex: `Relay(MyCustomName.relay1)=RELAYL01-123456.relay1`)

relay→get_advertisedValue()**YRelay****relay→advertisedValue()**

Returns the current value of the relay (no more than 6 characters).

js	function get_advertisedValue ()
cpp	string get_advertisedValue ()
m	-(NSString*) advertisedValue
pas	function get_advertisedValue (): string
vb	function get_advertisedValue () As String
cs	string get_advertisedValue ()
java	String get_advertisedValue ()
uwp	async Task<string> get_advertisedValue ()
py	def get_advertisedValue ()
php	function get_advertisedValue ()
es	function get_advertisedValue ()
cmd	YRelay target get_advertisedValue

Returns :

a string corresponding to the current value of the relay (no more than 6 characters).

On failure, throws an exception or returns Y_ADVERTISEDVALUE_INVALID.

relay→get_countdown()**YRelay****relay→countdown()**

Returns the number of milliseconds remaining before a pulse (delayedPulse() call) When there is no scheduled pulse, returns zero.

js	function get_countdown ()
cpp	s64 get_countdown ()
m	-(s64) countdown
pas	function get_countdown (): int64
vb	function get_countdown () As Long
cs	long get_countdown ()
java	long get_countdown ()
uwp	async Task<long> get_countdown ()
py	def get_countdown ()
php	function get_countdown ()
es	function get_countdown ()
cmd	YRelay target get_countdown

Returns :

an integer corresponding to the number of milliseconds remaining before a pulse (delayedPulse() call) When there is no scheduled pulse, returns zero

On failure, throws an exception or returns Y_COUNTDOWN_INVALID.

relay→**get_errorMessage()****YRelay****relay**→**errorMessage()**

Returns the error message of the latest error with the relay.

<code>js</code>	<code>function get_errorMessage()</code>
<code>cpp</code>	<code>string get_errorMessage()</code>
<code>m</code>	<code>-(NSString*) errorMessage</code>
<code>pas</code>	<code>function get_errorMessage(): string</code>
<code>vb</code>	<code>function get_errorMessage() As String</code>
<code>cs</code>	<code>string get_errorMessage()</code>
<code>java</code>	<code>String get_errorMessage()</code>
<code>py</code>	<code>def get_errorMessage()</code>
<code>php</code>	<code>function get_errorMessage()</code>
<code>es</code>	<code>function get_errorMessage()</code>

This method is mostly useful when using the Yoctopuce library with exceptions disabled.

Returns :

a string corresponding to the latest error message that occurred while using the relay object

relay→**get_errorType()****YRelay****relay**→**errorType()**

Returns the numerical error code of the latest error with the relay.

js	function get_errorType ()
cpp	YRETCODE get_errorType ()
pas	function get_errorType (): YRETCODE
vb	function get_errorType () As YRETCODE
cs	YRETCODE get_errorType ()
java	int get_errorType ()
py	def get_errorType ()
php	function get_errorType ()
es	function get_errorType ()

This method is mostly useful when using the Yoctopuce library with exceptions disabled.

Returns :

a number corresponding to the code of the latest error that occurred while using the relay object

relay→**get_friendlyName()****YRelay****relay**→**friendlyName()**

Returns a global identifier of the relay in the format `MODULE_NAME.FUNCTION_NAME`.

js	function get_friendlyName ()
cpp	string get_friendlyName ()
m	-(NSString*) friendlyName
cs	string get_friendlyName ()
java	String get_friendlyName ()
py	def get_friendlyName ()
php	function get_friendlyName ()
es	function get_friendlyName ()

The returned string uses the logical names of the module and of the relay if they are defined, otherwise the serial number of the module and the hardware identifier of the relay (for example: `MyCustomName.relay1`)

Returns :

a string that uniquely identifies the relay using logical names (ex: `MyCustomName.relay1`)

On failure, throws an exception or returns `Y_FRIENDLYNAME_INVALID`.

`relay→get_functionDescriptor()` `relay→functionDescriptor()`

YRelay

Returns a unique identifier of type YFUN_DESCR corresponding to the function.

js	function <code>get_functionDescriptor()</code>
cpp	YFUN_DESCR <code>get_functionDescriptor()</code>
m	-(YFUN_DESCR) <code>functionDescriptor</code>
pas	function <code>get_functionDescriptor()</code> : YFUN_DESCR
vb	function <code>get_functionDescriptor()</code> As YFUN_DESCR
cs	YFUN_DESCR <code>get_functionDescriptor()</code>
java	String <code>get_functionDescriptor()</code>
py	def <code>get_functionDescriptor()</code>
php	function <code>get_functionDescriptor()</code>
es	function <code>get_functionDescriptor()</code>

This identifier can be used to test if two instances of YFunction reference the same physical function on the same physical device.

Returns :

an identifier of type YFUN_DESCR.

If the function has never been contacted, the returned value is Y_FUNCTIONDESCRIPTOR_INVALID.

relay→get_functionId()**YRelay****relay→functionId()**

Returns the hardware identifier of the relay, without reference to the module.

js	function get_functionId ()
cpp	string get_functionId ()
m	-(NSString*) functionId
vb	function get_functionId () As String
cs	string get_functionId ()
java	String get_functionId ()
py	def get_functionId ()
php	function get_functionId ()
es	function get_functionId ()

For example `relay1`

Returns :

a string that identifies the relay (ex: `relay1`)

On failure, throws an exception or returns `Y_FUNCTIONID_INVALID`.

relay→**get_hardwareId()****YRelay****relay**→**hardwareId()**

Returns the unique hardware identifier of the relay in the form SERIAL . FUNCTIONID.

js	function get_hardwareId ()
cpp	string get_hardwareId ()
m	-(NSString*) hardwareId
vb	function get_hardwareId () As String
cs	string get_hardwareId ()
java	String get_hardwareId ()
py	def get_hardwareId ()
php	function get_hardwareId ()
es	function get_hardwareId ()

The unique hardware identifier is composed of the device serial number and of the hardware identifier of the relay (for example RELAYL01-123456 . relay1).

Returns :

a string that uniquely identifies the relay (ex: RELAYL01-123456 . relay1)

On failure, throws an exception or returns Y_HARDWAREID_INVALID.

relay→get_logicalName()**YRelay****relay→logicalName()**

Returns the logical name of the relay.

js	function get_logicalName ()
cpp	string get_logicalName ()
m	-(NSString*) logicalName
pas	function get_logicalName (): string
vb	function get_logicalName () As String
cs	string get_logicalName ()
java	String get_logicalName ()
uwp	async Task<string> get_logicalName ()
py	def get_logicalName ()
php	function get_logicalName ()
es	function get_logicalName ()
cmd	YRelay target get_logicalName

Returns :

a string corresponding to the logical name of the relay.

On failure, throws an exception or returns Y_LOGICALNAME_INVALID.

relay→get_maxTimeOnStateA()**YRelay****relay→maxTimeOnStateA()**

Retourne the maximum time (ms) allowed for \$THEFUNCTIONS\$ to stay in state A before automatically switching back in to B state.

js	function get_maxTimeOnStateA ()
cpp	s64 get_maxTimeOnStateA ()
m	-(s64) maxTimeOnStateA
pas	function get_maxTimeOnStateA (): int64
vb	function get_maxTimeOnStateA () As Long
cs	long get_maxTimeOnStateA ()
java	long get_maxTimeOnStateA ()
uwp	async Task<long> get_maxTimeOnStateA ()
py	def get_maxTimeOnStateA ()
php	function get_maxTimeOnStateA ()
es	function get_maxTimeOnStateA ()
cmd	YRelay target get_maxTimeOnStateA

Zero means no maximum time.

Returns :

an integer

On failure, throws an exception or returns Y_MAXTIMEONSTATEA_INVALID.

relay→get_maxTimeOnStateB()**YRelay****relay→maxTimeOnStateB()**

Retourne the maximum time (ms) allowed for \$THEFUNCTIONS\$ to stay in state B before automatically switching back in to A state.

js	function get_maxTimeOnStateB ()
cpp	s64 get_maxTimeOnStateB ()
m	-(s64) maxTimeOnStateB
pas	function get_maxTimeOnStateB (): int64
vb	function get_maxTimeOnStateB () As Long
cs	long get_maxTimeOnStateB ()
java	long get_maxTimeOnStateB ()
uwp	async Task<long> get_maxTimeOnStateB ()
py	def get_maxTimeOnStateB ()
php	function get_maxTimeOnStateB ()
es	function get_maxTimeOnStateB ()
cmd	YRelay target get_maxTimeOnStateB

Zero means no maximum time.

Returns :

an integer

On failure, throws an exception or returns Y_MAXTIMEONSTATEB_INVALID.

relay→get_module()**YRelay****relay→module()**

Gets the YModule object for the device on which the function is located.

js	function get_module ()
cpp	YModule * get_module ()
m	-(YModule*) module
pas	function get_module (): TModule
vb	function get_module () As YModule
cs	YModule get_module ()
java	YModule get_module ()
py	def get_module ()
php	function get_module ()
es	function get_module ()

If the function cannot be located on any module, the returned instance of YModule is not shown as online.

Returns :

an instance of YModule

relay→get_module_async()**YRelay****relay→module_async()**

Gets the YModule object for the device on which the function is located (asynchronous version).

```
js function get_module_async( callback, context)
```

If the function cannot be located on any module, the returned YModule object does not show as on-line.

This asynchronous version exists only in Javascript. It uses a callback instead of a return value in order to avoid blocking Firefox javascript VM that does not implement context switching during blocking I/O calls. See the documentation section on asynchronous Javascript calls for more details.

Parameters :

callback callback function that is invoked when the result is known. The callback function receives three arguments: the caller-specific context object, the receiving function object and the requested YModule object

context caller-specific object that is passed as-is to the callback function

Returns :

nothing : the result is provided to the callback.

relay→**get_output()****YRelay****relay**→**output()**

Returns the output state of the relays, when used as a simple switch (single throw).

js	function get_output ()
cpp	Y_OUTPUT_enum get_output ()
m	-(Y_OUTPUT_enum) output
pas	function get_output (): Integer
vb	function get_output () As Integer
cs	int get_output ()
java	int get_output ()
uwp	async Task<int> get_output ()
py	def get_output ()
php	function get_output ()
es	function get_output ()
cmd	YRelay target get_output

Returns :

either Y_OUTPUT_OFF or Y_OUTPUT_ON, according to the output state of the relays, when used as a simple switch (single throw)

On failure, throws an exception or returns Y_OUTPUT_INVALID.

relay→get_pulseTimer()**YRelay****relay→pulseTimer()**

Returns the number of milliseconds remaining before the relays is returned to idle position (state A), during a measured pulse generation.

js	function get_pulseTimer ()
cpp	s64 get_pulseTimer ()
m	-(s64) pulseTimer
pas	function get_pulseTimer (): int64
vb	function get_pulseTimer () As Long
cs	long get_pulseTimer ()
java	long get_pulseTimer ()
uwp	async Task<long> get_pulseTimer ()
py	def get_pulseTimer ()
php	function get_pulseTimer ()
es	function get_pulseTimer ()
cmd	YRelay target get_pulseTimer

When there is no ongoing pulse, returns zero.

Returns :

an integer corresponding to the number of milliseconds remaining before the relays is returned to idle position (state A), during a measured pulse generation

On failure, throws an exception or returns Y_PULSETIMER_INVALID.

relay→get_state()**YRelay****relay→state()**

Returns the state of the relays (A for the idle position, B for the active position).

js	function get_state ()
cpp	Y_STATE_enum get_state ()
m	-(Y_STATE_enum) state
pas	function get_state (): Integer
vb	function get_state () As Integer
cs	int get_state ()
java	int get_state ()
uwp	async Task<int> get_state ()
py	def get_state ()
php	function get_state ()
es	function get_state ()
cmd	YRelay target get_state

Returns :

either Y_STATE_A or Y_STATE_B, according to the state of the relays (A for the idle position, B for the active position)

On failure, throws an exception or returns Y_STATE_INVALID.

relay→get_stateAtPowerOn()**YRelay****relay→stateAtPowerOn()**

Returns the state of the relays at device startup (A for the idle position, B for the active position, UNCHANGED for no change).

js	function get_stateAtPowerOn ()
cpp	Y_STATEATPOWERON_enum get_stateAtPowerOn ()
m	-(Y_STATEATPOWERON_enum) stateAtPowerOn
pas	function get_stateAtPowerOn (): Integer
vb	function get_stateAtPowerOn () As Integer
cs	int get_stateAtPowerOn ()
java	int get_stateAtPowerOn ()
uwp	async Task<int> get_stateAtPowerOn ()
py	def get_stateAtPowerOn ()
php	function get_stateAtPowerOn ()
es	function get_stateAtPowerOn ()
cmd	YRelay target get_stateAtPowerOn

Returns :

a value among Y_STATEATPOWERON_UNCHANGED, Y_STATEATPOWERON_A and Y_STATEATPOWERON_B corresponding to the state of the relays at device startup (A for the idle position, B for the active position, UNCHANGED for no change)

On failure, throws an exception or returns Y_STATEATPOWERON_INVALID.

relay→get_userData()**YRelay****relay→userData()**

Returns the value of the userData attribute, as previously stored using method set_userData.

js	function get_userData ()
cpp	void * get_userData ()
m	-(id) userData
pas	function get_userData (): Tobject
vb	function get_userData () As Object
cs	object get_userData ()
java	Object get_userData ()
py	def get_userData ()
php	function get_userData ()
es	function get_userData ()

This attribute is never touched directly by the API, and is at disposal of the caller to store a context.

Returns :

the object stored previously by the caller.

relay→isOnline()**YRelay**

Checks if the relay is currently reachable, without raising any error.

js	function isOnline ()
cpp	bool isOnline ()
m	-(BOOL) isOnline
pas	function isOnline (): boolean
vb	function isOnline () As Boolean
cs	bool isOnline ()
java	boolean isOnline ()
py	def isOnline ()
php	function isOnline ()
es	function isOnline ()

If there is a cached value for the relay in cache, that has not yet expired, the device is considered reachable. No exception is raised if there is an error while trying to contact the device hosting the relay.

Returns :

`true` if the relay can be reached, and `false` otherwise

relay→isOnline_async()**YRelay**

Checks if the relay is currently reachable, without raising any error (asynchronous version).

```
js function isOnline_async( callback, context)
```

If there is a cached value for the relay in cache, that has not yet expired, the device is considered reachable. No exception is raised if there is an error while trying to contact the device hosting the requested function.

This asynchronous version exists only in Javascript. It uses a callback instead of a return value in order to avoid blocking the Javascript virtual machine.

Parameters :

- callback** callback function that is invoked when the result is known. The callback function receives three arguments: the caller-specific context object, the receiving function object and the boolean result
- context** caller-specific object that is passed as-is to the callback function

Returns :

nothing : the result is provided to the callback.

relay→load()**YRelay**

Preloads the relay cache with a specified validity duration.

js	function load (msValidity)
cpp	YRETCODE load (int msValidity)
m	-(YRETCODE) load : (int) msValidity
pas	function load (msValidity : integer): YRETCODE
vb	function load (ByVal msValidity As Integer) As YRETCODE
cs	YRETCODE load (ulong msValidity)
java	int load (long msValidity)
py	def load (msValidity)
php	function load (\$msValidity)
es	function load (msValidity)

By default, whenever accessing a device, all function attributes are kept in cache for the standard duration (5 ms). This method can be used to temporarily mark the cache as valid for a longer period, in order to reduce network traffic for instance.

Parameters :

msValidity an integer corresponding to the validity attributed to the loaded function parameters, in milliseconds

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→loadAttribute()**YRelay**

Returns the current value of a single function attribute, as a text string, as quickly as possible but without using the cached value.

js	function loadAttribute (attrName)
cpp	string loadAttribute (string attrName)
m	-(NSString*) loadAttribute : (NSString*) attrName
pas	function loadAttribute (attrName : string): string
vb	function loadAttribute () As String
cs	string loadAttribute (string attrName)
java	String loadAttribute (String attrName)
uwp	async Task<string> loadAttribute (string attrName)
py	def loadAttribute (attrName)
php	function loadAttribute (\$attrName)
es	function loadAttribute (attrName)

Parameters :

attrName the name of the requested attribute

Returns :

a string with the value of the the attribute

On failure, throws an exception or returns an empty string.

relay→load_async()**YRelay**

Preloads the relay cache with a specified validity duration (asynchronous version).

```
js function load_async( msValidity, callback, context)
```

By default, whenever accessing a device, all function attributes are kept in cache for the standard duration (5 ms). This method can be used to temporarily mark the cache as valid for a longer period, in order to reduce network traffic for instance.

This asynchronous version exists only in Javascript. It uses a callback instead of a return value in order to avoid blocking the Javascript virtual machine.

Parameters :

- msValidity** an integer corresponding to the validity of the loaded function parameters, in milliseconds
- callback** callback function that is invoked when the result is known. The callback function receives three arguments: the caller-specific context object, the receiving function object and the error code (or YAPI_SUCCESS)
- context** caller-specific object that is passed as-is to the callback function

Returns :

nothing : the result is provided to the callback.

relay→muteValueCallbacks()**YRelay**

Disables the propagation of every new advertised value to the parent hub.

js	function muteValueCallbacks ()
cpp	int muteValueCallbacks ()
m	-(int) muteValueCallbacks
pas	function muteValueCallbacks (): LongInt
vb	function muteValueCallbacks () As Integer
cs	int muteValueCallbacks ()
java	int muteValueCallbacks ()
uwp	async Task<int> muteValueCallbacks ()
py	def muteValueCallbacks ()
php	function muteValueCallbacks ()
es	function muteValueCallbacks ()
cmd	YRelay target muteValueCallbacks

You can use this function to save bandwidth and CPU on computers with limited resources, or to prevent unwanted invocations of the HTTP callback. Remember to call the `saveToFlash()` method of the module if the modification must be kept.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→nextRelay()**YRelay**

Continues the enumeration of relays started using `yFirstRelay()`.

js	function nextRelay ()
cpp	YRelay * nextRelay ()
m	-(YRelay*) nextRelay
pas	function nextRelay (): TYRelay
vb	function nextRelay () As YRelay
cs	YRelay nextRelay ()
java	YRelay nextRelay ()
uwp	YRelay nextRelay ()
py	def nextRelay ()
php	function nextRelay ()
es	function nextRelay ()

Returns :

a pointer to a `YRelay` object, corresponding to a relay currently online, or a `null` pointer if there are no more relays to enumerate.

relay→pulse()**YRelay**

Sets the relay to output B (active) for a specified duration, then brings it automatically back to output A (idle state).

js	function pulse (ms_duration)
cpp	int pulse (int ms_duration)
m	-(int) pulse : (int) ms_duration
pas	function pulse (ms_duration : LongInt): integer
vb	function pulse (ByVal ms_duration As Integer) As Integer
cs	int pulse (int ms_duration)
java	int pulse (int ms_duration)
uwp	async Task<int> pulse (int ms_duration)
py	def pulse (ms_duration)
php	function pulse (\$ms_duration)
es	function pulse (ms_duration)
cmd	YRelay target pulse ms_duration

Parameters :

ms_duration pulse duration, in milliseconds

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→registerValueCallback()**YRelay**

Registers the callback function that is invoked on every change of advertised value.

js	function registerValueCallback (callback)
cpp	int registerValueCallback (YRelayValueCallback callback)
m	-(int) registerValueCallback : (YRelayValueCallback) callback
pas	function registerValueCallback (callback : TYRelayValueCallback): LongInt
vb	function registerValueCallback () As Integer
cs	int registerValueCallback (ValueCallback callback)
java	int registerValueCallback (UpdateCallback callback)
uwp	async Task<int> registerValueCallback (ValueCallback callback)
py	def registerValueCallback (callback)
php	function registerValueCallback (\$callback)
es	function registerValueCallback (callback)

The callback is invoked only during the execution of `ySleep` or `yHandleEvents`. This provides control over the time when the callback is triggered. For good responsiveness, remember to call one of these two functions periodically. To unregister a callback, pass a null pointer as argument.

Parameters :

callback the callback function to call, or a null pointer. The callback function should take two arguments: the function object of which the value has changed, and the character string describing the new advertised value.

relay→**set_logicalName()****YRelay****relay**→**setLogicalName()**

Changes the logical name of the relay.

js	function set_logicalName (newval)
cpp	int set_logicalName (const string& newval)
m	-(int) setLogicalName : (NSString*) newval
pas	function set_logicalName (newval : string): integer
vb	function set_logicalName (ByVal newval As String) As Integer
cs	int set_logicalName (string newval)
java	int set_logicalName (String newval)
uwp	async Task<int> set_logicalName (string newval)
py	def set_logicalName (newval)
php	function set_logicalName (\$ newval)
es	function set_logicalName (newval)
cmd	YRelay target set_logicalName newval

You can use `yCheckLogicalName()` prior to this call to make sure that your parameter is valid. Remember to call the `saveToFlash()` method of the module if the modification must be kept.

Parameters :

newval a string corresponding to the logical name of the relay.

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→set_maxTimeOnStateA()**YRelay****relay→setMaxTimeOnStateA()**

Sets the maximum time (ms) allowed for \$THEFUNCTIONS\$ to stay in state A before automatically switching back in to B state.

js	function set_maxTimeOnStateA (newval)
cpp	int set_maxTimeOnStateA (s64 newval)
m	-(int) setMaxTimeOnStateA : (s64) newval
pas	function set_maxTimeOnStateA (newval : int64): integer
vb	function set_maxTimeOnStateA (ByVal newval As Long) As Integer
cs	int set_maxTimeOnStateA (long newval)
java	int set_maxTimeOnStateA (long newval)
uwp	async Task<int> set_maxTimeOnStateA (long newval)
py	def set_maxTimeOnStateA (newval)
php	function set_maxTimeOnStateA (\$ newval)
es	function set_maxTimeOnStateA (newval)
cmd	YRelay target set_maxTimeOnStateA newval

Use zero for no maximum time.

Parameters :

newval an integer

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→set_maxTimeOnStateB()**YRelay****relay→setMaxTimeOnStateB()**

Sets the maximum time (ms) allowed for \$THEFUNCTIONS\$ to stay in state B before automatically switching back in to A state.

js	function set_maxTimeOnStateB (newval)
cpp	int set_maxTimeOnStateB (s64 newval)
m	-(int) setMaxTimeOnStateB : (s64) newval
pas	function set_maxTimeOnStateB (newval : int64): integer
vb	function set_maxTimeOnStateB (ByVal newval As Long) As Integer
cs	int set_maxTimeOnStateB (long newval)
java	int set_maxTimeOnStateB (long newval)
uwp	async Task<int> set_maxTimeOnStateB (long newval)
py	def set_maxTimeOnStateB (newval)
php	function set_maxTimeOnStateB (\$ newval)
es	function set_maxTimeOnStateB (newval)
cmd	YRelay target set_maxTimeOnStateB newval

Use zero for no maximum time.

Parameters :

newval an integer

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→set_output()**YRelay****relay→setOutput()**

Changes the output state of the relays, when used as a simple switch (single throw).

js	function set_output (newval)
cpp	int set_output (Y_OUTPUT_enum newval)
m	-(int) setOutput : (Y_OUTPUT_enum) newval
pas	function set_output (newval : Integer): integer
vb	function set_output (ByVal newval As Integer) As Integer
cs	int set_output (int newval)
java	int set_output (int newval)
uwp	async Task<int> set_output (int newval)
py	def set_output (newval)
php	function set_output (\$newval)
es	function set_output (newval)
cmd	YRelay target set_output newval

Parameters :

newval either Y_OUTPUT_OFF or Y_OUTPUT_ON, according to the output state of the relays, when used as a simple switch (single throw)

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→**set_state()****YRelay****relay**→**setState()**

Changes the state of the relays (A for the idle position, B for the active position).

js	function set_state (newval)
cpp	int set_state (Y_STATE_enum newval)
m	-(int) setState : (Y_STATE_enum) newval
pas	function set_state (newval : Integer): integer
vb	function set_state (ByVal newval As Integer) As Integer
cs	int set_state (int newval)
java	int set_state (int newval)
uwp	async Task<int> set_state (int newval)
py	def set_state (newval)
php	function set_state (\$ newval)
es	function set_state (newval)
cmd	YRelay target set_state newval

Parameters :

newval either Y_STATE_A or Y_STATE_B, according to the state of the relays (A for the idle position, B for the active position)

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→set_stateAtPowerOn()**YRelay****relay→setStateAtPowerOn()**

Preset the state of the relays at device startup (A for the idle position, B for the active position, UNCHANGED for no modification).

js	function set_stateAtPowerOn (newval)
cpp	int set_stateAtPowerOn (Y_STATEATPOWERON_enum newval)
m	-(int) setStateAtPowerOn : (Y_STATEATPOWERON_enum) newval
pas	function set_stateAtPowerOn (newval : Integer): integer
vb	function set_stateAtPowerOn (ByVal newval As Integer) As Integer
cs	int set_stateAtPowerOn (int newval)
java	int set_stateAtPowerOn (int newval)
uwp	async Task<int> set_stateAtPowerOn (int newval)
py	def set_stateAtPowerOn (newval)
php	function set_stateAtPowerOn (\$ newval)
es	function set_stateAtPowerOn (newval)
cmd	YRelay target set_stateAtPowerOn newval

Remember to call the matching module `saveToFlash()` method, otherwise this call will have no effect.

Parameters :

newval a value among Y_STATEATPOWERON_UNCHANGED, Y_STATEATPOWERON_A and Y_STATEATPOWERON_B

Returns :

YAPI_SUCCESS if the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→**set_userData()****YRelay****relay**→**setUserData()**

Stores a user context provided as argument in the `userData` attribute of the function.

js	function set_userData (data)
cpp	void set_userData (void* data)
m	-(void) setUserData : (id) data
pas	procedure set_userData (data : Tobject)
vb	procedure set_userData (ByVal data As Object)
cs	void set_userData (object data)
java	void set_userData (Object data)
py	def set_userData (data)
php	function set_userData (\$data)
es	function set_userData (data)

This attribute is never touched by the API, and is at disposal of the caller to store a context.

Parameters :

data any kind of object to be stored

relay→unmuteValueCallbacks()**YRelay**

Re-enables the propagation of every new advertised value to the parent hub.

js	function unmuteValueCallbacks ()
cpp	int unmuteValueCallbacks ()
m	-(int) unmuteValueCallbacks
pas	function unmuteValueCallbacks (): LongInt
vb	function unmuteValueCallbacks () As Integer
cs	int unmuteValueCallbacks ()
java	int unmuteValueCallbacks ()
uwp	async Task<int> unmuteValueCallbacks ()
py	def unmuteValueCallbacks ()
php	function unmuteValueCallbacks ()
es	function unmuteValueCallbacks ()
cmd	YRelay target unmuteValueCallbacks

This function reverts the effect of a previous call to `muteValueCallbacks()`. Remember to call the `saveToFlash()` method of the module if the modification must be kept.

Returns :

YAPI_SUCCESS when the call succeeds.

On failure, throws an exception or returns a negative error code.

relay→wait_async()**YRelay**

Waits for all pending asynchronous commands on the module to complete, and invoke the user-provided callback function.

```
js function wait_async( callback, context)
es function wait_async( callback, context)
```

The callback function can therefore freely issue synchronous or asynchronous commands, without risking to block the Javascript VM.

Parameters :

callback callback function that is invoked when all pending commands on the module are completed. The callback function receives two arguments: the caller-specific context object and the receiving function object.

context caller-specific object that is passed as-is to the callback function

Returns :

nothing.

21. Troubleshooting

21.1. Where to start?

If it is the first time that you use a Yoctopuce module and you do not really know where to start, have a look at the Yoctopuce blog. There is a section dedicated to beginners ¹.

21.2. Linux and USB

To work correctly under Linux, the library needs to have write access to all the Yoctopuce USB peripherals. However, by default under Linux, USB privileges of the non-root users are limited to read access. To avoid having to run the *VirtualHub* as root, you need to create a new *udev* rule to authorize one or several users to have write access to the Yoctopuce peripherals.

To add a new *udev* rule to your installation, you must add a file with a name following the "`##-arbitraryName.rules`" format, in the `/etc/udev/rules.d` directory. When the system is starting, *udev* reads all the files with a `.rules` extension in this directory, respecting the alphabetical order (for example, the `"51-custom.rules"` file is interpreted AFTER the `"50-udev-default.rules"` file).

The `"50-udev-default"` file contains the system default *udev* rules. To modify the default behavior, you therefore need to create a file with a name that starts with a number larger than 50, that will override the system default rules. Note that to add a rule, you need a root access on the system.

In the `udev_conf` directory of the *VirtualHub* for Linux² archive, there are two rule examples which you can use as a basis.

Example 1: 51-yoctopuce.rules

This rule provides all the users with read and write access to the Yoctopuce USB peripherals. Access rights for all other peripherals are not modified. If this scenario suits you, you only need to copy the `"51-yoctopuce_all.rules"` file into the `/etc/udev/rules.d` directory and to restart your system.

```
# udev rules to allow write access to all users
# for Yoctopuce USB devices
```

¹ see: http://www.yoctopuce.com/EN/blog_by_categories/for-the-beginners

² <http://www.yoctopuce.com/FR/virtualhub.php>

```
SUBSYSTEM=="usb", ATTR{idVendor}=="24e0", MODE="0666"
```

Example 2: 51-yoctopuce_group.rules

This rule authorizes the "yoctogroup" group to have read and write access to Yoctopuce USB peripherals. Access rights for all other peripherals are not modified. If this scenario suits you, you only need to copy the "51-yoctopuce_group.rules" file into the "/etc/udev/rules.d" directory and restart your system.

```
# udev rules to allow write access to all users of "yoctogroup"
# for Yoctopuce USB devices
SUBSYSTEM=="usb", ATTR{idVendor}=="24e0", MODE="0664", GROUP="yoctogroup"
```

21.3. ARM Platforms: HF and EL

There are two main flavors of executable on ARM: HF (Hard Float) binaries, and EL (EABI Little Endian) binaries. These two families are not compatible at all. The compatibility of a given ARM platform with one of these two families depends on the hardware and on the OS build. ArmHL and ArmEL compatibility problems are quite difficult to detect. Most of the time, the OS itself is unable to make a difference between an HF and an EL executable and will return meaningless messages when you try to use the wrong type of binary.

All pre-compiled Yoctopuce binaries are provided in both formats, as two separate ArmHF et ArmEL executables. If you do not know what family your ARM platform belongs to, just try one executable from each family.

21.4. Powered module but invisible for the OS

If your Yocto-PowerRelay is connected by USB, if its blue led is on, but if the operating system cannot see the module, check that you are using a true USB cable with data wires, and not a charging cable. Charging cables have only power wires.

21.5. Another process named xxx is already using yAPI

If when initializing the Yoctopuce API, you obtain the *"Another process named xxx is already using yAPI"* error message, it means that another application is already using Yoctopuce USB modules. On a single machine only one process can access Yoctopuce modules by USB at a time. You can easily work around this limitation by using a VirtualHub and the network mode ³.

21.6. Disconnections, erratic behavior

If you Yocto-PowerRelay behaves erratically and/or disconnects itself from the USB bus without apparent reason, check that it is correctly powered. Avoid cables with a length above 2 meters. If needed, insert a powered USB hub ^{4 5}.

21.7. Damaged device

Yoctopuce strives to reduce the production of electronic waste. If you believe that your Yocto-PowerRelay is not working anymore, start by contacting Yoctopuce support by e-mail to diagnose the failure. Even if you know the device was damaged by mistake, Yoctopuce engineers might be able to repair it, and avoid creating electronic waste.

³ see: <http://www.yoctopuce.com/EN/article/error-message-another-process-is-already-using-yapi>

⁴ see: <http://www.yoctopuce.com/EN/article/usb-cables-size-matters>

⁵ see: <http://www.yoctopuce.com/EN/article/how-many-usb-devices-can-you-connect>

Waste Electrical and Electronic Equipment (WEEE) If you really want to get rid of your Yocto-PowerRelay, do not throw it away in a trash bin but bring it to a local WEEE recycling point. In this way, it will be disposed properly by a specialized WEEE recycling center.

22. Characteristics

You can find below a summary of the main technical characteristics of your Yocto-PowerRelay module.

Width	20 mm
Length	45 mm
Weight	12 g
USB connector	micro-B
Channels	1
Max switching current	5 A
Max switching power	1250 W
Max witholding voltage	400 V DC
Supported Operating Systems	Windows, Linux (Intel + ARM), Mac OS X, Android
Drivers	no driver needed
API / SDK / Libraries (USB+TCP)	C++, Objective-C, C#, VB .NET, Delphi, Python, Java/Android
API / SDK / Libraries (TCP only)	Javascript, Node.js, PHP, Java
RoHS	yes
USB Vendor ID	0x24E0
USB Device ID	0x000D
Suggested enclosure	YoctoBox-Short-Thick-Black

All dimensions are in mm
Toutes les dimensions sont en mm
